From the Author

A Journey from “Black Box” to Builder

This book proves a fundamental truth: **you don’t need billion-dollar infrastructure to build powerful AI**. The content you’re about to explore was based on an AI course and workshops where students and scientists built and fine-tuned their first language models, refined through workshops where researchers, from complete beginners to advanced programmers, trained models using their own field data, and validated by hundreds of practitioners who created specialized AI systems on local or cloud GPUs.

Origins

Despite the excitement around ChatGPT and GPT-4/5, most researchers and practitioners use them cautiously. Privacy concerns, API costs, lack of domain knowledge, and inability to customize created a gap between “AI is amazing” and “AI is useful for my work.”

This gap became obvious in my “**Generative AI for Science**” course, where students from geoscience, law, history, biology, and small businesses asked: *How can I build an AI that understands my domain, runs on my infrastructure, and costs less than my coffee budget?*

What began as lecture notes evolved through real problems—a geologist fine-tuning a model on geohazard data, a legal researcher processing court documents, a historian analyzing archaic letters, and a small business building multilingual customer support. This document has been tested through research workshops, industry bootcamps, open-source collaboration with the MiniMind and GPT-2 communities, and real production deployments running on consumer hardware.

How This Book Is Different

This is not an AI research paper. It’s a **builder’s manual**, it is a **step-by-step guide** for anyone being told “you can’t do AI without massive resources.”

Understanding before optimizing: Chapter 2 takes you through building GPT from scratch—every attention head, every layer, every parameter. Once you understand how to *build* it, you’ll understand how to *customize* it. Chapter 3 shows why fine-tuning is more practical than training from scratch.

Click, run, learn, modify: All codes are provided in .ipynb format which can be opened simply in **Google Colab notebooks**, or local Jupyter Notebook. No installations, no expensive hardware for learning. Click, run, see a language model train, modify—all in your browser, for free.

Real constraints, real solutions: Examples from actual deployments: a code documentation generator handling production codebases, a multilingual support system. We discuss costs in dollars, training time in hours, hardware in specific GPU models.

Honest about trade-offs: Learn when to use small models vs. APIs, local vs. cloud deployment, building from scratch vs. fine-tuning. We cover what works, what doesn't, and why.

What You'll Learn

By the end of this book, you will learn how to:

- **Build** a simple and small GPT-like model from scratch and understand transformers deeply
- **Pretrain** models on custom datasets (125M-350M parameters on consumer hardware)
- **Fine-tune** using full supervised fine-tuning
- **Align** with Direct Preference Optimization (DPO)
- **Deploy** production systems with safety, monitoring, and ethics
- **Navigate** the complete pipeline: data -> architecture -> training -> evaluation -> deployment

More importantly, you'll develop the confidence to know: **"I can build this myself."**

One person with a laptop (or \$10/month Colab), curiosity, and willingness to learn can build production-quality language models that solve real problems.

Let's Begin

The barrier between "AI user" and "AI builder" is thinner than you think. It's not talent or resources—it's understanding and practice.

By Chapter 2, you'll have built a tiny but working GPT model. By Chapter 3, you'll understand why fine-tuning is revolutionary. By Chapter 10, you'll have trained a small but complete modern language model. By Chapter 12, you'll have deployed production systems.

But tools are only as good as the wisdom with which we wield them. Build models that respect privacy, acknowledge limitations, and fail gracefully. Let the AI propose; let humans decide; let ethics guide.

The future of AI isn't just in the hands of big tech. It's also in yours, if you are willing to.

Now, let's build something remarkable together.

Getting Started

 **Most important** When you begin to read each chapter, please download that chapter's Google Colab codes from <https://rewriting.ai/bookcode/slm.php>

Requirements: A web browser and curiosity. Everything runs in Google Colab free tier T4, L4 or A100 GPUs for learning.

Time Investment: Chapter 2 (60 min) -> Chapter 3 (30 min) -> Complete pipeline (20-30 hrs) -> Production (10-15 hrs)

Total cost: Under \$50 to production expertise. Less than a new video game.

Further Learning: to encourage you to explore further, in some chapters, I have added up-to-date references and further readings—research papers, tutorials, open-source projects, and community resources—updated to 2025 to support your continued learning journey.

Advanced User for some trainings, I also provided some running scripts for HPC multiple GPUs environments.

Important note

A small language model (SLM) alone cannot replace a mighty LLM, practically many people begin to combine both in real world projects.

Let's begin. 

AI Use Disclaimer

This work was developed with the assistance of modern AI language models, including **ChatGPT**, **Claude**, **Gemini**, and **DeepSeek**. These systems were only used to:

1. Improve clarity of writing, including corrections to my English grammar and syntax.
2. Support text organization and formatting, including Markdown structure, embedded python code blocks, output results and visual styling.
3. Assist with code formatting, proofreading, and debugging processes.

All conceptual content, working flow, research interpretations, conclusions, and final decisions remain my own.

ALL code examples enclosed via an external website were tested and verified at the time of completion (**November 2025**). However, programming libraries, runtime environments, and external APIs may change over time. Code behavior in future environments may differ, and readers are encouraged to adapt as necessary.

No AI system used in this process held authority over technical correctness, academic interpretation, or authorship intent.

The author retains full responsibility for the final content.

Chapter 1: Introduction

Welcome to the World of Small Language Models

You've probably used ChatGPT, Claude, DeepSeek, or Gemini. Maybe you've been amazed by their abilities--and frustrated by their limitations. Perhaps you've wondered: *Those giant models are a mysterious black box, and I have no ideas what's happening under the hood; What if I could build my own AI model, trained on my specific domain, running on my own computer, with complete control over the data?*

Good news: **You can.** And you don't need to be a PhD in machine learning field to do it.

This book will show you how to build and customize small language models (SLMs)--AI models that are powerful enough to be genuinely useful, yet small enough to train and run on affordable hardware. Whether you're a researcher wanting to process scientific papers, a historian analyzing historical texts, or simply curious about how AI really works, you're in the right place.

Why Small Language Models Matter

The Giant Model Problem

The biggest AI models today--GPT-4/5, Claude, Gemini--contain hundreds of billions of parameters. They're incredibly powerful, but they come with some serious drawbacks:

Cost: Running queries directly or through APIs can cost hundreds to thousands of dollars per month for heavy users. Training or fine-tuning these models? That's millions of dollars.

Privacy: Your data goes to someone else's servers. If you're working with confidential research data, patient records, or proprietary business information, this is a dealbreaker.

Control: You can't modify how they work. If GPT-4 doesn't understand your field's terminology or keeps making the same mistakes, you're stuck with it.

Availability: API services can go down, change pricing, or discontinue access. Your research or business depends on someone else's decisions.

Speed: Sending requests over the Internet and waiting in queue can mean delays of seconds or even minutes.

The Small Model Advantage

Small language models—typically ranging from 125 million to 7 billion parameters—offer a different trade-off:

- ✓ **Run locally:** On your own computer or server
- ✓ **Full control:** Train on your data, customize behavior, keep everything private
- ✓ **Affordable:** Train for \$50-500 or less, run for pennies
- ✓ **Fast:** No network latency, instant responses
- ✓ **Specialized:** Can outperform giant models on specific tasks

Here's the key insight: For many real-world tasks, you don't need a model that can write poetry, solve advanced math, and explain quantum physics. You need a model that's really good at *your specific task*.

A 350-million parameter model fine-tuned on medical literature can outperform GPT-4 at answering specific questions about drug interactions—while running on a laptop or an intranet server.

Use Cases: When to Use SLMs vs Giant LLMs

Let's be practical about when small models make sense.

Use Small Language Models When:

1. You have domain-specific needs

- Analyzing legal documents with specialized terminology
- Processing scientific papers in your field (geology, chemistry, linguistics)
- Understanding historical texts or non-English languages
- Working with industry jargon (finance, healthcare, engineering)

Example: A geologist needs to extract mineral composition data from thousands of research papers. A small model trained on geology literature will recognize terms like “plagioclase feldspar” and “phenocryst” better than a general model.

2. Privacy is critical

- Medical records
- Legal case files
- Proprietary business data
- Unpublished research
- Personal information

Example 1: A hospital wants to summarize patient notes. They cannot send this data to OpenAI's servers due to HIPAA regulations. A local small model solves this.

Example 2: A farm using a small vision model to detect early plant diseases directly on-site, without internet access, ensures farmers get real-time alerts while keeping costs low.

3. You need speed and reliability

- Real-time applications
- High-volume processing (thousands of documents)
- Offline environments
- Consistent performance without API rate limits

Example: A customer service system processing 10,000 support tickets daily would cost \$500-1,000/month via API. A local model costs \$50/month in electricity.

4. Budget constraints

- Academic research projects
- Non-profit organizations
- Individual researchers
- Small businesses
- Student projects

Example: A graduate student needs to analyze 50,000 historical newspaper articles. API costs would exceed \$2,000. Training a small model costs \$100.

5. Customization is important

- Specific output formats
- Consistent behavior for your use case
- Integration with other tools
- Control over model updates

Stick with Giant LLMs When:

- ✗ You need **broad general knowledge** across many domains
- ✗ You need **complex reasoning** and multi-step problem solving
- ✗ You need **up-to-date information** via agents (current events, recent discoveries)
- ✗ You're doing **exploratory work** without clear requirements
- ✗ **Convenience matters more than cost, or privacy** and you have the budget

The Bottom Line: Giant LLMs are generalists and powerful. Small models are specialists and portable. If you can clearly define your task and provide relevant training data, a small model will likely serve you better.

What You'll Build in This Book

This isn't a theoretical textbook. By the end, you'll learn **how actually train and deploy** your own language models. Here's what you'll accomplish:

Phase 1: Understanding the Foundation (Chapter 2)

Before fine-tuning, you need to understand what you're working with. In Chapter 2, you'll **build a tiny but complete GPT model from scratch**. You could run through every line of code yourself and see exactly how language models work under the hood.

Time required: 60-90 minutes

What you'll learn:

- How transformers actually work
- What “attention” means and why it's powerful
- How to build neural networks from the ground up
- The complete architecture of GPT (similar to GPT-2 and MiniMind)

What you'll create: A ~10M parameter only character-level model that generates Shakespeare-like text

Why this matters: Once you understand how to build a model from scratch, fine-tuning pre-trained models becomes intuitive. You'll know exactly what's happening inside the black box.

Phase 2: Your First Fine-Tune (Chapter 3)

Now that you understand the architecture, you'll experience the power of transfer learning. In just 30 minutes, you'll fine-tune a GPT-2 small model (125M parameters) for a specific task.

Time required: 30 minutes

What you'll learn:

- The difference between training from scratch vs fine-tuning
- How to use pre-trained models effectively
- Transfer learning principles
- Why fine-tuning is so much faster and cheaper

What you'll create: A specialized model (e.g., recipe writer, product description generator) that adapts GPT-2/3's knowledge to your specific domain

Why this matters: You'll see firsthand why fine-tuning is the practical approach for most real-world applications.

Phase 3: Understanding Data & Configuration (Chapters 4-5)

You'll learn:

- How to prepare datasets (cleaning, formatting, tokenization)
- How to configure model architecture (size, layers, parameters)
- Understanding GPT-2-like models in depth
- How to choose the right size for your use case

Real project: Design and configure your own GPT-2/3-like model.

Phase 4: Training & Evaluation (Chapters 6-7)

- How to pretrain models from scratch
- How to evaluate if your model is working well
- How to troubleshoot common problems
- When to stop training

Real project: Pretrain a GPT-2-like model (125M-350M parameters) on your prepared data.

Phase 5: The MiniMind Case Study (Chapters 8-10)

After understanding the fundamentals with GPT models, you'll apply everything to build a complete modern SLM using **MiniMind** as your example. You'll follow the complete three-stage training pipeline:

Chapter 8: Pretrain MiniMind

- Understanding MiniMind architecture (26M-218M parameters)
- Pretraining from scratch on English-based text corpus
- **Real project:** Pretrain MiniMind-small (26M) or MiniMind (109M)

Chapter 9: Supervised Fine-Tuning (SFT)

- Full fine-tuning for maximum quality
- When to use each technique
- **Real project:** Apply SFT to your pretrained MiniMind-like model

Chapter 10: Direct Preference Optimization (DPO)

- Advanced alignment techniques
- Preparing preference datasets
- **Real project:** Apply DPO to your SFT'd MiniMind-style model

Phase 6: Production Deployment (Chapters 11-12)

You'll learn to:

- Optimize models to run faster and use less memory
- Deploy models as APIs or web services
- Understand costs, ethics, and limitations
- Build real production systems

Final projects: Three complete deployments:

1. Domain-specific Q&A bot (medical, legal, or scientific)
2. Code documentation generator
3. Multilingual assistant

Modern SLM Architectures: GPT-2 & MiniMind

Throughout this book, you'll work with two proven architectures:

GPT-2 (OpenAI, 2019):

- 125M to 1.5B parameters
- Well-documented, widely supported
- Excellent starting point for learning
- Available in multiple sizes for experimentation
- **Used in Chapters 3-7 for foundational learning**

MiniMind (Recent, Efficient):

- 26M to 218M parameters
- Optimized for smaller compute
- Modern training techniques
- Three-stage training: Pretrain -> SFT -> DPO
- **Case study in Chapters 8-10 for complete training pipeline**

Both architectures share core transformer principles you'll learn in Chapter 2. The choice depends on your resources and use case.

Hardware Requirements and Cost Breakdown

Let's talk honestly about what you'll need. The good news: it's more accessible than you think.

Minimum Requirements (Getting Started)

For Chapters 2-3 (Learning the Basics):

- **Computer:** Any laptop from the last 5 years
- **RAM:** 16GB minimum (32GB comfortable)
- **GPU:** Not required! You can use free Google Colab
- **Cost:** \$0

Yes, you can literally start with nothing but a web browser and a Google account.

Recommended Setup (Serious Work)

For Chapters 4-12:

Option 1: Cloud GPU (Easiest)

- **Service:** Google Colab Pro, RunPod, Lambda Labs, or Paperspace
- **GPU:** NVIDIA A100 (40GB) or L40S
- **Cost:** \$1-3 per hour
- **Total for book:** \$50-150 (assuming 50-100 hours of training)

Option 2: Local GPU (Best for Long-Term)

- **GPU:** NVIDIA RTX 4090 (24GB) or RTX 3090 (24GB)
- **Cost:** \$1,200-1,600 (used) or \$1,600-2,000 (new)(price changes daily)
- **Why this works:** You own it, no ongoing costs, full privacy
- **Electricity:** ~\$10-20/month for heavy use

Option 3: Mac with Apple Silicon (M1/M2/M3/M4)

- Works surprisingly well for using models up to 7B parameters
- No additional cost if you already have the computer
- Slower than NVIDIA GPUs but functional, such as via Ollama.

What Can You Train With Each Setup?

Hardware	Model Size	Training Time	Cost
Google Colab Free	10M params (Ch 2)	1 hour	\$0
Google Colab Free	125M params (Ch 3)	10 minutes	\$0
Google Colab Pro (\$10/mo)	350M params	4-8 hours	\$10/month
Cloud A100	1B params	8-16 hours	\$8-48 per run
RTX 4090 (local)	1B-3B params	12-24 hours	\$15-30 electricity

Realistic Cost Examples

Example 1: Student (Tight Budget)

- Uses Google Colab Free for Chapters 2-3
- Subscribes to Colab Pro (\$10/month) for 3 months
- Trains three 350M parameter models
- **Total cost: \$30**

Good News: Starting July 2025, Google has begun to offer a limited number of completely free, 1-year Colab Pro subscriptions to faculty and students at U.S.-based higher education institutions, check: <https://blog.google/outreach-initiatives/education/colab-higher-education/>

Example 2: Researcher (Moderate Budget)

- Rents cloud GPU for 50 hours across 2 months
- Trains five models (350M-1B parameters)
- **Total cost: \$75-150**

Example 3: Professional (Long-Term Investment)

- Buys used RTX 3090 for \$1,200
- Trains dozens of models over years
- **Upfront cost: \$1,200; ongoing: ~\$10/month electricity**

To Start, What You DON'T Need

- ✗ A server farm
- ✗ Enterprise-level infrastructure
- ✗ A computer science degree
- ✗ Specialized hardware beyond a good GPU
- ✗ A team of engineers

One person with a consumer GPU can train entry-level production-quality models.

Your Learning Journey: The Path Ahead

The Book's Structure

****Part I: Foundations (Chapters 1-3)****

- └ Ch 1: Introduction (you are here)
- └ Ch 2: Build GPT **from Scratch** (understand the engine)
- └ Ch 3: Quick Start -- Fine-Tune GPT-2 (see the difference)

****Part II: Training **from Scratch** -- Deep Dive (Chapters 4-7)****

- └ Ch 4: Dataset Preparation
- └ Ch 5: Architecture Configuration
- └ Ch 6: Training Loop & Monitoring
- └ Ch 7: Evaluation & Benchmarks

****Part III: The MiniMind Case Study (Chapters 8-10)****

- └ Ch 8: Stage 1 -- Pretraining MiniMind
- └ Ch 9: Stage 2 -- Supervised Fine-Tuning (SFT)
- └ Ch 10: Stage 3 -- Direct Preference Optimization (DP0)

****Part IV: Production (Chapters 11-12)****

- └ Ch 11: Production Deployment
- └ Ch 12: Real-World Projects & Ethics

Two Learning Paths

Path A: Deep Understanding (Recommended)

- Start with Chapter 2 - Build GPT from scratch
- Do Chapter 3 - See how fine-tuning differs from pretraining
- This gives you the foundation to understand everything else
- Then Chapters 4-7 for training fundamentals
- Then Chapters 8-10 for the complete MiniMind case study
- Finally Chapters 11-12 for production deployment

Path B: Quick Start (If You're Impatient)

- Skim Chapter 2 to get the concepts
- Jump to Chapter 3 for fine-tuning in 30 minutes
- See immediate results
- Come back to Chapters 2 and 4-7 when you want deeper understanding
- Then follow Chapters 8-10 for the complete training pipeline

Is This Book for You?

This book is designed for:

- ✓ **Researchers and academics** who want to apply AI to their field
- ✓ **College and graduate students** working on data-intensive projects
- ✓ **Domain experts** (doctors, lawyers, scientists) who want custom AI
- ✓ **Curious beginners** willing to learn by doing
- ✓ **Small business owners** who want affordable AI solutions
- ✓ **Anyone who values privacy, control, and customization**

You don't need to be a programmer. Every code example is provided in full—you can copy, paste, or just click and run it. We'll explain what each part does, but you can get results even if you don't understand every line.

What you DO need:

- Willingness to experiment and troubleshoot
- Basic computer skills (installing software, using command line is helpful but not required)
- Patience (training models takes time)
- Curiosity about how AI works

How to Use This Book

If you want to understand deeply: Start with Chapter 2 and build GPT from scratch. Then do Chapter 3 to experience fine-tuning. This gives you the foundation to understand everything else. Then Chapters 4-7. Then Chapters 8-10 for the complete MiniMind training pipeline. This is the recommended path.

If you're in a hurry: Skim Chapter 2 for concepts, then jump to Chapter 3 to fine-tune a model in 30 minutes. You'll see immediate results. Come back to earlier chapters when you want deeper understanding.

If you're methodical: Read chapters in order. Each builds on the previous one.

If you're goal-oriented: Skim to Chapter 12 (Real-World Projects), pick the project closest to your needs, then work backwards through the chapters that cover the techniques you need.

All codes are available online: Every example in this book is in an online repository with Jupyter/-Colab notebooks you can run immediately. Access codes are provided at the end of each chapter.

Ready? Let's start by understanding what we're actually building.

Next: Chapter 2–Build GPT from scratch and understand how it really works

Chapter 2: Let's Build GPT from Scratch

Understanding What You'll Build Before You Fine-Tune

In this chapter, we're going to build a small GPT (Generative Pre-trained Transformer) from the ground up. By the end, you'll have created your own language model that can generate Shakespeare-like text.

This isn't just theory - you'll write every line of code yourself and understand what each piece does.

What you'll need:

- A web browser
- A Google account (for free GPU access)
- 30-60 minutes
- Curiosity and patience

What you'll learn:

- How language models actually work under the hood
- What "attention" means in transformers
- How to build and train a neural network from scratch
- Why GPT is so powerful

Part 1: The Big Picture

What is a Language Model?

A language model is simply a program that predicts the next word (or character) in a sequence. Given "The cat sat on the", it should predict "mat" (or something sensible, like "floor" or "sofa").

How it learns:

1. Read lots of text
2. Try to predict each next character
3. Get feedback on mistakes
4. Adjust internal "weights" to do better
5. Repeat millions of times

That's it. Everything else is optimization to make this work better.

(A detailed video demonstration by Andrej Karpathy is available at <https://youtu.be/kCc8FmEb1nY>, the following simple codes are derived from this demo)

Why Characters Instead of Words?

We'll build a **character-level** model that predicts the next character, not word. Why?

- ✓ **Simpler**: Only 65 unique characters vs 50,000+ words
- ✓ **Smaller vocabulary**: Less memory needed
- ✓ **Can invent words**: Learns patterns, not just memorization
- ✓ **Perfect for learning**: See results faster

The principles are identical for word-level models—just a bigger vocabulary.

Part 2: Setting Up Your Workspace

Step 1: Open Google Colab

1. Go to colab.research.google.com
2. Click “**New Notebook**”
3. Go to **Runtime** -> **Change runtime type**
4. Select “**T4 GPU**”
5. Click **Save**

You have to run the above steps to make sure you can use Google Colab!

Note: This book's codes are available online: <https://rewriting.ai/bookcode/slm.php>

Step 2: Download Shakespeare Dataset

Same as the Youtube demo, we'll train on Shakespeare's works—about 1MB of text, perfect for learning.

```
```python
Download the tiny Shakespeare dataset, or any other book text.

!wget https://raw.githubusercontent.com/karpathy/char-rnn/master/data/tinyshakespeare/input.txt

Read and inspect it
with open('input.txt', 'r', encoding='utf-8') as f:
 text = f.read()

print(f"Dataset length: {len(text):,} characters")
print("\nFirst 500 characters:")
print(text[:500])
```
```

Output:

Dataset length: 1,115,394 characters

First 500 characters:

First Citizen:

Before we proceed **any** further, hear me speak.

All:

Speak, speak.

First Citizen:

You are **all** resolved rather to die than to famish?

On the left side, you can click the Files folder icon, there should be a file called “input.txt” there.

To add one or more code cells, you just need to click “+Code” one or more times.

Part 3: Tokenization - Converting Text to Numbers

Computers don't understand text—they work with numbers. We need to convert characters to integers.

Building Our Vocabulary,

```
# Get all unique characters in our dataset
chars = sorted(list(set(text)))
vocab_size = len(chars)

print(f"Vocabulary size: {vocab_size}")
print(f"All characters: {''.join(chars)}")
```

Output:

Vocabulary size: 65

All characters: **!\$&',-.:;?ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz**

Creating Encoder and Decoder

```

# Create mappings
stoi = {ch: i for i, ch in enumerate(chars)} # string to integer
itos = {i: ch for i, ch in enumerate(chars)} # integer to string

# Encoder: text → numbers
encode = lambda s: [stoi[c] for c in s]

# Decoder: numbers → text
decode = lambda l: ''.join([itos[i] for i in l])

# Test it
encoded = encode("Hello")
print(f"'Hello' encoded: {encoded}")
print(f"Decoded back: '{decode(encoded)}'")

```

Output:

```

'Hello' encoded: [20, 43, 50, 50, 53]
Decoded back: 'Hello'

```

Encoding the Entire Dataset

```

1 import torch
2
3 # Encode all text and convert to PyTorch tensor
4 data = torch.tensor(encode(text), dtype=torch.long)
5
6 print(f"Data shape: {data.shape}")
7 print(f"First 100 encoded characters: {data[:100]}")

```

Part 4: Train/Validation Split

Never test on your training data! Split into training (90%) and validation (10%) sets.

```

1 n = int(0.9 * len(data))
2 train_data = data[:n]
3 val_data = data[n:]
4
5 print(f"Training examples: {len(train_data):,}")
6 print(f"Validation examples: {len(val_data):,}")

```

Part 5: Understanding Context Windows

A language model doesn't see infinite history—just a fixed **context window** (block size).

```

python
block_size = 8 # Maximum context length

# Example: show training examples
x = train_data[:block_size]
y = train_data[1:block_size + 1]

print("Training examples with context:")
for t in range(block_size):
    context = x[:t+1]
    target = y[t]
    print(f"Context: {decode(context.tolist())!r:20} → Target: {decode([target.item()])!r}")

```

Output:

```

Context: 'F'           → Target: 'i'
Context: 'Fi'          → Target: 'r'
Context: 'Fir'         → Target: 's'
Context: 'Firs'        → Target: 't'
Context: 'First'       → Target: ' '
Context: 'First '      → Target: 'C'
Context: 'First C'     → Target: 'i'
Context: 'First Ci'    → Target: 't'

```

Key insight: From a single block of text, we get 8 training examples! Each position learns to predict the next character given all previous ones.

Part 6: Batching for Efficiency

Process multiple sequences in parallel for speed.

```

torch.manual_seed(1337) # For reproducibility
batch_size = 4 # Process 4 sequences at once
block_size = 8 # Each sequence is 8 characters long

def get_batch(split):
    """Generate a batch of training data"""
    data = train_data if split == 'train' else val_data

    # Pick random starting positions
    ix = torch.randint(len(data) - block_size, (batch_size,))

    # Stack sequences into batches
    x = torch.stack([data[i:i+block_size] for i in ix])
    y = torch.stack([data[i+1:i+block_size+1] for i in ix])

    return x, y

```

```
# Get a batch
xb, yb = get_batch('train')

print(f"Input batch shape: {xb.shape}") # (batch_size, block_size)
print(f"Target batch shape: {yb.shape}")
print(f"\nFirst sequence in batch:")
print(f"Input: {decode(xb[0].tolist())!r}")
print(f"Target: {decode(yb[0].tolist())!r}")
```

Output:

```
Input batch shape: torch.Size([4, 8])
Target batch shape: torch.Size([4, 8])
```

```
First sequence in batch:
Input: "when I w"
Target: "hen I wa"
```

Part 7: A Simple Baseline - The Bigram Model

Before building the full transformer, let's start with the simplest possible model: predict the next character based on only the current character (ignoring all context).

```
```python
import torch.nn as nn
from torch.nn import functional as F

class BigramLanguageModel(nn.Module):
 """Simplest possible language model"""

 def __init__(self, vocab_size):
 super().__init__()
 # Each token predicts logits for next token
 self.token_embedding_table = nn.Embedding(vocab_size, vocab_size)

 def forward(self, idx, targets=None):
 # idx: (B, T) tensor of token indices
 # logits: (B, T, C) tensor of predictions
 logits = self.token_embedding_table(idx)

 if targets is None:
 loss = None
 else:
 # Reshape for cross-entropy loss
 B, T, C = logits.shape
 logits = logits.view(B*T, C)
 targets = targets.view(B*T)
```

```

 loss = F.cross_entropy(logits, targets)

 return logits, loss

def generate(self, idx, max_new_tokens):
 """Generate new tokens"""
 for _ in range(max_new_tokens):
 # Get predictions
 logits, _ = self(idx)
 # Focus on last time step
 logits = logits[:, -1, :] # (B, C)
 # Convert to probabilities
 probs = F.softmax(logits, dim=-1)
 # Sample from distribution
 idx_next = torch.multinomial(probs, num_samples=1)
 # Append to sequence
 idx = torch.cat((idx, idx_next), dim=1)

 return idx

Create model
model = BigramLanguageModel(vocab_size)
logits, loss = model(xb, yb)

print(f"Logits shape: {logits.shape}")
print(f"Initial loss: {loss.item():.4f}")
print(f"Expected loss: {-torch.log(torch.tensor(1.0/vocab_size)):.4f}")
...

```

### Understanding the loss:

- Random guessing:  $\text{loss} = -\ln(1/65) \approx 4.17$
- Our untrained model:  $\sim 4.17$  (it's guessing randomly without pretraining!)
- After training: should be much lower

### Generate Before Training

```

Generate 100 characters from untrained model
context = torch.zeros((1, 1), dtype=torch.long)
generated = model.generate(context, max_new_tokens=100)
print(decode(generated[0].tolist()))

```

### Output (gibberish, as expected):

```
Sr?qP-QWktXoL&jLDJg0LVz'RIoDqHdhsV&vLLxat...
```

As you can see they are meaningless.

## Part 8: Training the Bigram Model

```
Setup optimizer
optimizer = torch.optim.AdamW(model.parameters(), lr=1e-3)

Training loop
batch_size = 32

for steps in range(10000):
 # Get batch
 xb, yb = get_batch('train')

 # Forward pass
 logits, loss = model(xb, yb)

 # Backward pass
 optimizer.zero_grad(set_to_none=True)
 loss.backward()
 optimizer.step()

 # Print progress
 if steps % 1000 == 0:
 print(f"Step {steps}: loss = {loss.item():.4f}")

print(f"\nFinal loss: {loss.item():.4f}")
```

### Output:

```
Step 0: loss = 4.7158
Step 1000: loss = 2.5124
Step 2000: loss = 2.4823
...
Step 9000: loss = 2.4651

Final loss: 2.4643
```

### Generate After Training

```
context = torch.zeros((1, 1), dtype=torch.long)
generated = model.generate(context, max_new_tokens=500)
print(decode(generated[0].tolist()))
```

### Output (better, but still poor):

```
CEng ay,
Theyomy t blll,
Wear'd tove
And whe f tha t ble nthe me,
```

**Why is it bad?** The bigram model has **no memory**--each prediction only sees one character. “Th” should predict “e”, but our model doesn’t see the “T”!

## Part 9: The Mathematical Trick - Self-Attention

We need characters to “talk to each other.” This is **self-attention**.

### Concept: Weighted Averages

Before attention, let’s understand weighted averages with a simple trick:

```
torch.manual_seed(42)
B, T, C = 4, 8, 2 # Batch, Time, Channels
x = torch.randn(B, T, C)

We want: x[b,t] = average of x[b, 0:t+1]
Inefficient way (loops):
xbow = torch.zeros((B, T, C))
for b in range(B):
 for t in range(T):
 xprev = x[b, :t+1] # All previous tokens
 xbow[b, t] = torch.mean(xprev, dim=0)

print("Using loops:")
print(xbow[0]) # First batch element
```

###Efficient way using matrix multiplication:

```
Create lower triangular matrix
wei = torch.tril(torch.ones(T, T))
wei = wei / wei.sum(1, keepdim=True) # Normalize rows

print("Weight matrix:")
print(wei)

Matrix multiply
xbow2 = wei @ x # (T, T) @ (B, T, C) → (B, T, C)

print("\nUsing matrix multiply:")
print(xbow2[0])

Check they're the same
print(f"\nAre they equal? {torch.allclose(xbow, xbow2)}")
```

**Output:**

```
Weight matrix:
tensor([[1.0000, 0.0000, 0.0000, ..., 0.0000],
 [0.5000, 0.5000, 0.0000, ..., 0.0000],
 [0.3333, 0.3333, 0.3333, ..., 0.0000],
 ...,
 [0.1250, 0.1250, 0.1250, ..., 0.1250]])
```

Are they equal? **True**

**Key insight:** Matrix multiplication can compute weighted averages in parallel!

**Using Softmax for Data-Dependent Weights**

```
Version 3: Use softmax
tril = torch.tril(torch.ones(T, T))
wei = torch.zeros((T, T))
wei = wei.masked_fill(tril == 0, float('-inf')) # Mask future
wei = F.softmax(wei, dim=-1) # Normalize
xbow3 = wei @ x

print(torch.allclose(xbow, xbow3)) # True
```

**Part 10: Implementing Self-Attention**

Now the magic: make weights **data-dependent**!

```
torch.manual_seed(1337)
B, T, C = 4, 8, 32 # Bigger embedding dimension
x = torch.randn(B, T, C)

Single Head of Self-Attention
head_size = 16

Create Query, Key, Value projections
key = nn.Linear(C, head_size, bias=False)
query = nn.Linear(C, head_size, bias=False)
value = nn.Linear(C, head_size, bias=False)

k = key(x) # (B, T, 16)
q = query(x) # (B, T, 16)
v = value(x) # (B, T, 16)

Compute attention scores ("affinities")
wei = q @ k.transpose(-2, -1) # (B, T, T)
```

```

Scale by sqrt(head_size) for stable gradients
wei = wei * (head_size ** -0.5)

Mask future tokens (for autoregressive generation)
tril = torch.tril(torch.ones(T, T))
wei = wei.masked_fill(tril == 0, float('-inf'))

Softmax to get attention weights
wei = F.softmax(wei, dim=-1)

Weighted aggregation of values
out = wei @ v # (B, T, 16)

print(f"Output shape: {out.shape}")
print(f"\nAttention weights for first token:")
print(wei[0, 0]) # Should be [1, 0, 0, ..., 0]
print(f"\nAttention weights for last token:")
print(wei[0, -1]) # Attends to all previous tokens

```

### What just happened?

1. **Query:** “What am I looking for?”
2. **Key:** “What do I contain?”
3. **Value:** “What do I actually communicate?”
4. **Attention:** Query-Key tells us how relevant each past token is
5. **Output:** Weighted sum of Values based on relevance

## Part 11: Building a Complete Transformer Block

### Multi-Head Attention

```

class Head(nn.Module):
 """One head of self-attention"""

 def __init__(self, head_size):
 super().__init__()
 self.key = nn.Linear(n_embd, head_size, bias=False)
 self.query = nn.Linear(n_embd, head_size, bias=False)
 self.value = nn.Linear(n_embd, head_size, bias=False)
 self.register_buffer('tril', torch.tril(torch.ones(block_size, block_size)))
 self.dropout = nn.Dropout(dropout)

 def forward(self, x):
 B, T, C = x.shape
 k = self.key(x)
 q = self.query(x)
 v = self.value(x)

```

```

 # Compute attention
 wei = q @ k.transpose(-2, -1) * (C ** -0.5)
 wei = wei.masked_fill(self.tril[:T, :T] == 0, float('-inf'))
 wei = F.softmax(wei, dim=-1)
 wei = self.dropout(wei)

 # Weighted aggregation
 out = wei @ v
 return out

class MultiHeadAttention(nn.Module):
 """Multiple attention heads in parallel"""

 def __init__(self, num_heads, head_size):
 super().__init__()
 self.heads = nn.ModuleList([Head(head_size) for _ in range(num_heads)])
 self.proj = nn.Linear(n_embd, n_embd)
 self.dropout = nn.Dropout(dropout)

 def forward(self, x):
 # Run all heads in parallel and concatenate
 out = torch.cat([h(x) for h in self.heads], dim=-1)
 out = self.dropout(self.proj(out))
 return out

```

## Feed-Forward Network

```

```python
class FeedForward(nn.Module):
    """Simple feed-forward network"""

    def __init__(self, n_embd):
        super().__init__()
        self.net = nn.Sequential(
            nn.Linear(n_embd, 4 * n_embd), # Expand
            nn.ReLU(),
            nn.Linear(4 * n_embd, n_embd), # Project back
            nn.Dropout(dropout),
        )

    def forward(self, x):
        return self.net(x)
```

```

## Transformer Block

```

python
class Block(nn.Module):
 """Transformer block: attention + feed-forward"""

 def __init__(self, n_embd, n_head):
 super().__init__()
 head_size = n_embd // n_head
 self.sa = MultiHeadAttention(n_head, head_size)
 self.ffwd = FeedForward(n_embd)
 self.ln1 = nn.LayerNorm(n_embd)
 self.ln2 = nn.LayerNorm(n_embd)

 def forward(self, x):
 # Residual connections + layer norm
 x = x + self.sa(self.ln1(x))
 x = x + self.ffwd(self.ln2(x))
 return x

```

## Part 12: The Complete GPT Model

```

class GPTLanguageModel(nn.Module):
 def __init__(self):
 super().__init__()
 self.token_embedding_table = nn.Embedding(vocab_size, n_embd)
 self.position_embedding_table = nn.Embedding(block_size, n_embd)
 self.blocks = nn.Sequential(*[Block(n_embd, n_head=n_head) for _ in range(n_layer)])
 self.ln_f = nn.LayerNorm(n_embd)
 self.lm_head = nn.Linear(n_embd, vocab_size)

 def forward(self, idx, targets=None):
 B, T = idx.shape

 # Embeddings
 tok_emb = self.token_embedding_table(idx) # (B, T, C)
 pos_emb = self.position_embedding_table(torch.arange(T, device=idx.device)) # (T, C)
 x = tok_emb + pos_emb # (B, T, C)

 # Transformer blocks
 x = self.blocks(x)
 x = self.ln_f(x)

 # Output projection
 logits = self.lm_head(x) # (B, T, vocab_size)

 if targets is None:
 loss = None
 else:
 B, T, C = logits.shape
 logits = logits.view(B*T, C)
 targets = targets.view(B*T)
 loss = F.cross_entropy(logits, targets)

```

```

 return logits, loss

 def generate(self, idx, max_new_tokens):
 for _ in range(max_new_tokens):
 # Crop context to block_size
 idx_cond = idx[:, -block_size:]
 # Get predictions
 logits, _ = self(idx_cond)
 # Focus on last time step
 logits = logits[:, -1, :]
 # Sample
 probs = F.softmax(logits, dim=-1)
 idx_next = torch.multinomial(probs, num_samples=1)
 # Append
 idx = torch.cat((idx, idx_next), dim=1)

 return idx

```

## Part 13: Training the Full Model

```

Hyperparameters
batch_size = 16 # how many independent sequences will we process in parallel?
block_size = 32 # what is the maximum context length for predictions?
max_iters = 5000
eval_interval = 100
learning_rate = 1e-3
device = 'cuda' if torch.cuda.is_available() else 'cpu'
eval_iters = 200
n_embd = 64
n_head = 4
n_layer = 4
dropout = 0.2

Helper function for evaluation

val_losses = []

for iter in range(max_iters):
 # Evaluate loss periodically
 if iter % eval_interval == 0 or iter == max_iters - 1:
 losses = estimate_loss()
 train_losses.append(losses['train'])
 val_losses.append(losses['val'])
 print(f"step {iter}: train loss {losses['train']:.4f}, val loss {losses['val']:.4f}")

 # Get batch
 xb, yb = get_batch('train')

 # Forward & backward
 logits, loss = model(xb, yb)
 optimizer.zero_grad(set_to_none=True)
 loss.backward()
 optimizer.step()

Generate
context = torch.zeros((1, 1), dtype=torch.long, device=device)
print(decode(model.generate(context, max_new_tokens=500)[0].tolist()))

```

### Expected output after training:

LEONTES:

What's the matter?

Lord:

I cannot tell you what I did for him,  
But I was a man of such a noble mind,  
And so the devil did make me a fool.

KING RICHARD II:

Well, sir, I'll tell you what:  
The king hath sent you to the Tower.

Much better! It learned:

- Character patterns
- Word boundaries
- Capitalization
- Basic sentence structure
- Even some “meaning”

## Part 14: Plot Training Loss vs. Epochs

```
import matplotlib.pyplot as plt
```

```
plt.plot(range(0, max_iters + 1, eval_interval), train_losses, label='Training Loss')
plt.plot(range(0, max_iters + 1, eval_interval), val_losses, label='Validation Loss')
plt.xlabel('Epochs')
plt.ylabel('Loss')
plt.legend()
plt.title('Training and Validation Loss')
plt.show()
```

# Understanding What We Built

## The Architecture Stack

## Key Components

| Component            | Purpose                          | Analogy                        |
|----------------------|----------------------------------|--------------------------------|
| Token Embedding      | Convert characters to vectors    | Looking up words in dictionary |
| Position Embedding   | Add position information         | Page numbers in a book         |
| Self-Attention       | Let tokens communicate           | Cocktail party conversation    |
| Multi-Head           | Multiple attention perspectives  | Looking from different angles  |
| Feed-Forward         | Process information individually | Thinking about what you heard  |
| Layer Norm           | Stabilize training               | Keeping everyone on same scale |
| Residual Connections | Allow gradient flow              | Shortcuts through deep network |

## How This Relates to What's Coming

The tiny GPT you just built uses the same core principles as the models you'll work with throughout this book:

**GPT-2 (Chapters 3-7):**

- 125M to 1.5B parameters
- Uses subword (BPE) tokenization instead of characters
- More layers (12-48 vs our 4), larger embeddings (768-1600 vs our 64)
- Trained on billions of tokens instead of 1MB
- **But the architecture? Nearly identical to what you just built!**

**MiniMind (Chapters 8-10):**

- 26M to 218M parameters
- Also uses subword tokenization
- Optimized for efficiency with modern training techniques
- Three-stage training: Pretrain → SFT → DPO
- **Same transformer architecture you now understand!**

**The main differences are scale, not structure:**

| What You Built   | GPT-2 Small           | MiniMind              |
|------------------|-----------------------|-----------------------|
| 10M params       | 125M params           | 26-218M params        |
| 4 layers         | 12 layers             | 6-12 layers           |
| 64 embedding dim | 768 embedding dim     | 512-768 embedding dim |
| Character tokens | 50,257 subword tokens | 6,400-50,000 tokens   |
| 1MB data         | 40GB data             | Varies by task        |

Understanding what you built makes fine-tuning (Chapter 3) and training from scratch (Chapters 4-10) much more intuitive!

**Why This Matters for Fine-Tuning**

Now you understand what you'll fine-tune in Chapter 3:

- ✓ **Embeddings:** Already learned character/token representations
- ✓ **Attention heads:** Already learned what to pay attention to
- ✓ **Feed-forward layers:** Already learned patterns

Fine-tuning just adjusts these slightly for your specific task—much faster than training from scratch!

## Exercises

### 1. Experiment with hyperparameters

```
Try different values:
n_embd = 128 # vs 64
n_layer = 6 # vs 4
n_head = 6 # vs 4
```

#### What happens?

- More parameters = better results but slower training
- Watch for overfitting (validation loss increases while training loss decreases)

### 2. Try different datasets

- Your own writing
- Code from GitHub
- Song lyrics
- Any text file you have!

Just replace the wget command with your own data file.

### 3. Implement temperature sampling

```

python
In generate(), after computing logits:
temperature = 0.8 # Try values between 0.1 and 2.0
logits = logits / temperature
probs = F.softmax(logits, dim=-1)

```

### Temperature effects:

- Higher ( $>1.0$ ) = more creative/random
- Lower ( $<1.0$ ) = more deterministic/safe
- Try 0.5, 0.8, 1.0, 1.5, and 2.0 to see the difference!

## Common Issues

**Problem:** “CUDA out of memory”

**Solution:** Reduce `batch_size` (try 8 or 4) or `n_embd` (try 32 or 48)

**Problem:** Loss isn't decreasing

**Solution:**

- Check learning rate (try  $3e-4$  or  $1e-4$ )
- Increase training steps (try 10000 or 20000)
- Verify your data loaded correctly

**Problem:** Generated text is repetitive

**Solution:**

- Use temperature sampling (see Exercise 3)
- Increase model size
- Train longer

**Problem:** Training is very slow

**Solution:**

- Make sure GPU is enabled (Runtime  $\square$  Change runtime type  $\square$  GPU)
- Reduce `batch_size` if GPU memory is maxed out
- Reduce `eval_iters` (try 50 instead of 200)

## What You Built

Congratulations! You just built:

- ✓ A complete GPT architecture from scratch
- ✓ Self-attention mechanism
- ✓ Multi-head attention
- ✓ Transformer blocks
- ✓ A working language model that generates coherent text

### Model stats:

- ~10M parameters (exact number depends on your hyperparameters)
- Trained on 1MB of Shakespeare (~1.1M characters)
- Can generate coherent text in Shakespeare's style
- Understands basic language structure and patterns

### What's remarkable:

- You can run every line of code yourself
- You understand every component
- This is the same architecture used by GPT-2, GPT-3, and modern LLMs
- The only difference is scale!

## Key Takeaways

- **Attention is all you need:** Self-attention lets tokens communicate effectively, see Vaswani et al. (2017).
- **Scale is key:** More parameters + more data = better results
- **Position matters:** Position embeddings add crucial location information
- **Residual connections:** Enable deep networks by allowing gradient flow
- **Layer normalization:** Stabilizes training and speeds convergence
- **Autoregressive generation:** Generate one token at a time, each conditioning on all previous tokens
- **The architecture is universal:** GPT-2, GPT-3, MiniMind all use these same building blocks

### What you now understand:

- How transformers work from first principles
- Why attention is so powerful
- How language models learn and generate
- The difference between model architecture and scale

- Why fine-tuning works (you're adjusting weights that already know language!)

## Next Steps

**Next:** Chapter 3–Quick Start: Fine-Tune GPT-2 in 30 minutes and see the difference between pretraining and fine-tuning □

In Chapter 3, you'll experience the power of transfer learning. Instead of training a model from scratch (which took 5000+ steps to get reasonable results), you'll load a pre-trained GPT-2 model and fine-tune it for a specific task in just 30 minutes. You'll see firsthand why fine-tuning is the practical approach for most real-world applications.

# Chapter 3: Quick Start–Fine-Tune Your First Model

## From Building to Customizing

In Chapter 2, you built a complete GPT-like small model from scratch and trained it on 1.1 MB Shakespeare text. You understand how transformers work, what attention does, and how language models learn.

Now here's the beautiful part: you don't have to build from scratch every time. In this chapter, you'll learn to take a **pre-trained** model and **fine-tune** it for a specific task--teaching an existing "language expert" to become a "recipe expert" instead.

This is what makes modern AI so practical: build once, customize infinitely.

### What you'll accomplish:

- Fine-tune GPT-2 (124/125M parameters) in 30 minutes
- Understand transfer learning in practice
- Experience the dramatic difference between training from scratch vs fine-tuning
- See immediate, practical results

### What you'll need:

- A web browser
- A Google account (for free GPU access)
- 30 minutes
- The knowledge from Chapter 2 (you now understand what's happening under the hood)

## Where This Fits in Your Learning Journey

You are here:

## Part I: Foundations

- Chapter 1: Introduction ✓
- Chapter 2: Build GPT **from Scratch** ✓
- Chapter 3: Quick Start -- Fine-Tune GPT-2 ← YOU ARE HERE

Coming **next**:

Part II: Training **from Scratch** -- Deep Dive (Chapters 4-7)

Part III: The MiniMind Case Study (Chapters 8-10)

### This chapter's purpose:

- **Quick win:** See fine-tuning results in 30 minutes
- **Contrast:** Experience the difference between pretraining (slow) and fine-tuning (fast)
- **Motivation:** Understand why Parts II and III matter

After this quick experience, you'll dive deep into data preparation, architecture configuration, and training fundamentals (Chapters 4-7) before applying everything to build a complete modern SLM with MiniMind (Chapters 8-10).

## Why Fine-Tune Instead of Building from Scratch?

In Chapter 2, you trained a model from scratch. It took thousands of iterations and you still got a relatively small model. Let's compare approaches:

| Approach                      | Training Time | Data Needed | Cost              | Use Case                     |
|-------------------------------|---------------|-------------|-------------------|------------------------------|
| <b>From Scratch</b><br>(Ch 2) | Hours/Days    | 10-100GB+   | \$100-<br>10,000+ | New language,<br>unique task |
| <b>Fine-Tuning</b><br>(Ch 3)  | Minutes/Hours | 1-100MB     | \$0-50            | Specialized<br>domain        |

### Key insight from Chapter 2: Your model learned:

1. Basic language patterns (grammar, word boundaries)
2. Some vocabulary and syntax
3. Character-level patterns

**What fine-tuning does:** Keeps all that knowledge, just adjusts the model weights slightly for your specific style/domain.

### Analogy:

- Training from scratch = Teaching a child English from birth (Chapter 2)
- Fine-tuning = Teaching an English speaker to write recipes (Chapter 3)

## Step 1: Open Google Colab

Same as Chapter 2:

1. Go to [colab.research.google.com](https://colab.research.google.com)
2. Click **New Notebook**
3. Go to **Runtime -> Change runtime type**
4. Select **T4 GPU**

Again, if you do not want to copy and paste codes line by line, you can download the code from <https://rewriting.ai/bookcode/slm.php>

## Step 2: Install Required Libraries

Unlike Chapter 2 where we built everything from scratch, now we'll use Hugging Face's Transformers library—a collection of pre-trained models ready to fine-tune.

```
```python
# Install required libraries
!pip install transformers datasets accelerate -q

print("✓ Libraries installed successfully!")
```
```

**What this does:**

- **transformers:** Pre-trained models (GPT-2, BERT, Llama, etc.)
- **datasets:** Easy data loading and processing
- **accelerate:** Makes training faster

**Expected time:** 30–60 seconds

## Step 3: Load a Pre-trained Model

Remember in Chapter 2 when you initialized random weights and trained them? Now we're loading weights that OpenAI already trained on billions of words.

```

from transformers import GPT2LMHeadModel, GPT2Tokenizer
from transformers import Trainer, TrainingArguments
from transformers import DataCollatorForLanguageModeling
import torch

Load the pretrained GPT-2 model and tokenizer
model_name = "gpt2" # This is the 125M parameter version

print(f"Loading {model_name}...")
tokenizer = GPT2Tokenizer.from_pretrained(model_name)
model = GPT2LMHeadModel.from_pretrained(model_name)

Set padding token (GPT-2 doesn't have one by default)
tokenizer.pad_token = tokenizer.eos_token

print(f"✓ Model loaded: {model.num_parameters():,} parameters")
print(f"✓ Model size: {model.num_parameters() / 1e6:.0f}M parameters")

```

### What this does:

- Downloads GPT-2 (125 million parameters--about 12x bigger than your Chapter 2 tiny model)
- Sets up the tokenizer (similar to the encode/decode functions you built in Chapter 2)
- Configures padding

### Important note about model access:

- **GPT-2 is completely open** - no account or token needed
- **Some other models require a Hugging Face token**, such as Meta's Llama models, Mistral models, or any model marked as "gated" on Hugging Face. Some models even need you to submit a request and sign an agreement online. I would suggest you go ahead to get your own "HF\_TOKEN". You can save it on your Google colab, just click the KEY on the left.

### Comparison to Chapter 2:

```

Chapter 2: You created this
class GPTLanguageModel(nn.Module):
 def __init__(self):
 self.token_embedding_table = nn.Embedding(vocab_size, n_embd)
 # ... rest of architecture

Chapter 3: OpenAI already trained this
model = GPT2LMHeadModel.from_pretrained(model_name)

```

**Expected time:** 15-30 seconds (downloads ~500MB)

**Output you'll see:**

- ✓ Model loaded: 124,439,808 parameters
- ✓ Model size: 124M parameters

## Step 4: Prepare Your Dataset

Same concept as Chapter 2's Shakespeare data, but now with recipes:

```
Sample recipe dataset
recipes = [
 "Preheat oven to 350°F. Mix flour, sugar, and eggs in a large bowl. Pour into greased pan. Bake
 ↪ for 25 minutes until golden brown.",
 "Boil water in a large pot. Add pasta and cook for 8-10 minutes. Drain and toss with olive oil and
 ↪ garlic.",
 "Heat olive oil in a skillet over medium heat. Add diced onions and cook until translucent. Add
 ↪ minced garlic and cook for 1 minute.",
 "Whisk eggs with milk and a pinch of salt. Pour into hot buttered pan. Scramble gently until just
 ↪ set.",
 "Combine ground beef with breadcrumbs, egg, and seasonings. Form into patties. Grill for 5 minutes
 ↪ per side.",
 "Slice vegetables into uniform pieces. Toss with oil and spices. Roast at 400°F for 20-25 minutes,
 ↪ stirring halfway.",
 "Melt butter in saucepan over low heat. Add flour and whisk constantly for 2 minutes. Gradually
 ↪ add milk while whisking.",
 "Season chicken breasts with salt and pepper. Heat oil in pan and cook 6-7 minutes per side until
 ↪ internal temperature reaches 165°F.",
 "Bring broth to a simmer. Add rice and reduce heat to low. Cover and cook for 18 minutes without
 ↪ lifting lid.",
 "Cream butter and sugar until light and fluffy. Add eggs one at a time, beating well after each
 ↪ addition.",
 "Sauté mushrooms in butter until golden. Add white wine and reduce by half. Finish with cream and
 ↪ fresh herbs.",
 "Blanch vegetables in boiling salted water for 2 minutes. Immediately transfer to ice bath to stop
 ↪ cooking.",
 "Dice potatoes into 1-inch cubes. Parboil for 5 minutes, drain, then roast at 425°F until crispy.",
 "Marinate meat in mixture of soy sauce, ginger, and garlic for at least 30 minutes. Pat dry before
 ↪ cooking.",
 "Toast spices in dry pan until fragrant, about 1-2 minutes. Grind in spice grinder or mortar and
 ↪ pestle.",
 "Proof yeast in warm water with a pinch of sugar for 5 minutes until foamy. Mix with flour and
 ↪ knead for 10 minutes.",
 "Sear steak in hot cast iron skillet for 3 minutes per side. Let rest for 5 minutes before slicing
 ↪ against the grain.",
 "Simmer sauce over low heat, stirring occasionally, until reduced and thickened, about 15-20
 ↪ minutes.",
 "Steam vegetables in bamboo steamer for 5-7 minutes until tender-crisp. Season with sesame oil and
 ↪ soy sauce.",
 "Fold beaten egg whites gently into batter using a rubber spatula. Pour into prepared pan and bake
 ↪ immediately.",
]

Create more training data by repeating
training_texts = recipes * 10 # 200 total examples
```

```
print(f"✓ Dataset prepared: {len(training_texts)} training examples")
print(f"✓ Sample text: {training_texts[0][:80]}...")
```

## Comparison to Chapter 2:

```
Chapter 2: Character-level encoding you built
encode = lambda s: [stoi[c] for c in s]
data = torch.tensor(encode(text), dtype=torch.long)

Chapter 3: Pre-built tokenizer (word pieces)
Does the same thing but better!
```

**Want to customize?** Replace the recipes list with your own text:

- Scientific paper abstracts from your field
- Customer service responses
- Legal document templates
- Poetry in a specific style
- Code examples

## Step 5: Tokenize the Data

Remember in Chapter 2 when you built the stoi and itos dictionaries? The tokenizer does the same thing, but with subwords instead of characters.

```
```python
from datasets import Dataset

# Convert to Hugging Face Dataset format
dataset_dict = {"text": training_texts}
dataset = Dataset.from_dict(dataset_dict)

# Tokenize the dataset
def tokenize_function(examples):
    return tokenizer(
        examples["text"],
        truncation=True,
        max_length=128, # Similar to block_size in Chapter 2
        padding="max_length",
    )

tokenized_dataset = dataset.map(
    tokenize_function,
    batched=True,
    remove_columns=dataset.column_names,
```

```
)

print("✓ Data tokenized successfully!")
print(f" Total sequences: {len(tokenized_dataset)}")

**What this does:**

- Converts text (tokens) into numbers that the model can process
- Sets maximum length to 128 tokens (roughly 100 words)
- Subword tokenization (BPE) splits each of most English words into about 1.3–1.4 tokens
- Pads shorter sequences to uniform length

**Connection to Chapter 2:**

```python
Chapter 2: Your character-level tokens
"Hello" -> [20, 43, 50, 50, 53]

Chapter 3: GPT-2's subword tokens
"Hello" -> [15496] # One token for the whole word!
```

## Step 6: Fine-Tune the Model

Here's where the magic happens. Unlike Chapter 2 where you trained for thousands of steps, fine-tuning converges much faster.

```
Set up data collator for language modeling
data_collator = DataCollatorForLanguageModeling(
 tokenizer=tokenizer,
 mlm=False, # Causal language modeling (like Chapter 2)
)

Configure training parameters
training_args = TrainingArguments(
 output_dir="./recipe-gpt2",
 overwrite_output_dir=True,
 num_train_epochs=3, # Just 3 passes through data
 per_device_train_batch_size=4,
 save_steps=500,
 save_total_limit=2,
 learning_rate=5e-5, # Lower than Chapter 2's 3e-4
 logging_steps=50,
 report_to="none",
)

Create the Trainer
trainer = Trainer(
 model=model,
 args=training_args,
 train_dataset=tokenized_dataset,
```

```
data_collator=data_collator,
)

Start training
print("Starting fine-tuning...")
print("This will take about 5-10 minutes on a T4 GPU.\n")

trainer.train()

print("\n✓ Fine-tuning complete!")
```

Key differences from Chapter 2:

Aspect	Chapter 2 (From Scratch)	Chapter 3 (Fine-tuning)
Starting point	Random weights	Pre-trained weights
Learning rate	3e-4 (higher)	5e-5 (lower)
Epochs needed	5,000-10,000 steps	3 epochs (~150 steps)
Training time	Hours	Minutes
Loss starts at	~4.17 (random)	~2.5 (already good)

**Expected time:** 5-10 minutes

What you’ll see:

```
Starting fine-tuning...
This will take about 5-10 minutes on a T4 GPU.

Epoch 1/3: [=====] 100% Loss: 2.456
Epoch 2/3: [=====] 100% Loss: 1.987
Epoch 3/3: [=====] 100% Loss: 1.743

✓ Fine-tuning complete!
```

**Why the loss is already low:** The model already understands language from its pre-training—it just needs to adjust weights for recipe-style writing.

Step 7: Save Your Model

```
Save the fine-tuned model
model.save_pretrained("./recipe-gpt2-final")
tokenizer.save_pretrained("./recipe-gpt2-final")

print("✓ Model saved to ./recipe-gpt2-final")
```

On the left side, if you click the Files folder, you will see two new folders there: “recipe-gpt2” and “recipe-gpt2-final”:

```
recipe-gpt2-final/
├─ config.json
├─ generation_config.json
├─ merges.txt
├─ model.safetensors
├─ special_tokens_map.json
├─ tokenizer_config.json
└─ vocab.json
```

## Step 8: Test Your Model

Now for the exciting part—let’s see what your model can do.

```
Function to generate text
def generate_recipe_instruction(prompt, max_length=100):
 """Generate recipe instructions based on a prompt"""
 # Encode the prompt
 inputs = tokenizer.encode(prompt, return_tensors="pt")

 # Move to GPU if available
 if torch.cuda.is_available():
 inputs = inputs.to("cuda")
 model.to("cuda")

 # Generate (similar to Chapter 2's generate method)
 outputs = model.generate(
 inputs,
 max_length=max_length,
 num_return_sequences=1,
 no_repeat_ngram_size=2,
 temperature=0.8, # Controls randomness
 top_p=0.9, # Nucleus sampling
 do_sample=True,
 pad_token_id=tokenizer.eos_token_id,
)
 # Decode and return
 generated_text = tokenizer.decode(outputs[0], skip_special_tokens=True)
 return generated_text
```

```
Test with different prompts
prompts = [
 "Heat oil in a pan and",
 "Preheat the oven to",
 "Mix the ingredients in",
 "Season the chicken with",
]

print("Testing the fine-tuned model:\n")
print("=" * 70)

for prompt in prompts:
 result = generate_recipe_instruction(prompt, max_length=80)
 print(f"\nPrompt: {prompt}")
 print(f"Generated: {result}")
 print("-" * 70)
```

### Sample output you might see:

Testing the fine-tuned model:

```
=====
Prompt: Heat oil in a pan and
Generated: Heat oil in a pan and add diced onions. Cook until
translucent, about 5 minutes. Add minced garlic and cook for 1
minute until fragrant.
```

```

Prompt: Preheat the oven to
Generated: Preheat the oven to 375°F. Arrange vegetables on baking
sheet in a single layer. Roast for 20-25 minutes, stirring halfway
through.
```

```

Prompt: Mix the ingredients in
Generated: Mix the ingredients in a large bowl until well combined.
Pour batter into greased pan. Bake for 30 minutes or until a
toothpick comes out clean.
```

```

Prompt: Season the chicken with
Generated: Season the chicken with salt, pepper, and paprika. Heat
oil in skillet over medium-high heat. Cook 6-7 minutes per side
until golden brown.
```

Notice: The model is now generating recipe-style instructions!

## Step 9: Compare With Original GPT-2

Let's prove fine-tuning worked by comparing with the original model:

```

Load the original GPT-2 for comparison
print("Loading original GPT-2 for comparison...\n")
original_model = GPT2LMHeadModel.from_pretrained("gpt2")

def generate_with_original(prompt, max_length=100):
 """Generate text with the original, non-fine-tuned model"""
 inputs = tokenizer.encode(prompt, return_tensors="pt")

 if torch.cuda.is_available():
 inputs = inputs.to("cuda")
 original_model.to("cuda")

 outputs = original_model.generate(
 inputs,
 max_length=max_length,
 num_return_sequences=1,
 no_repeat_ngram_size=2,
 temperature=0.8,
 top_p=0.9,
 do_sample=True,
 pad_token_id=tokenizer.eos_token_id,
)

 return tokenizer.decode(outputs[0], skip_special_tokens=True)

Compare side-by-side
test_prompt = "Heat oil in a pan and"

print("=" * 70)
print(f"Prompt: '{test_prompt}'\n")

original_output = generate_with_original(test_prompt, max_length=80)
finetuned_output = generate_recipe_instruction(test_prompt, max_length=80)

print("ORIGINAL GPT-2:")
print(original_output)
print("\n" + "-" * 70 + "\n")
print("YOUR FINE-TUNED MODEL:")
print(finetuned_output)
print("=" * 70)

```

### Sample comparison:

=====

Prompt: 'Heat oil in a pan and'

ORIGINAL GPT-2:

Heat oil **in** a pan **and** let it sit **for** about 20 minutes before you start to cook the food. You can also add some spices to the oil **if** you want, but I don't **think that's** necessary.

-----

YOUR FINE-TUNED MODEL:

Heat oil **in** a pan **and** add diced onions. Cook until translucent, about 5 minutes. Add garlic **and** sauté **for** 1 minute. Season **with** salt **and** pepper to taste.

=====

(Note: due to the nature of LLMs, your outputs may be slightly different)

**See the difference?**

- Original model: Conversational, casual, rambling
- Fine-tuned model: Concise, instructional, recipe-style

## Understanding What Just Happened

### Transfer Learning Explained

Remember the GPT architecture from Chapter 2:

Input -> Embeddings -> Transformer Blocks -> Output

**What was already trained (from GPT-2's pre-training):**

1. **Token embeddings:** Understanding of 50,000+ words
2. **Position embeddings:** How position affects meaning
3. **Attention heads:** What to pay attention to
4. **Feed-forward networks:** Pattern recognition
5. **Language structure:** Grammar, syntax, semantics

**What you fine-tuned:**

- Slight adjustments to ALL of the above
- New “preferences” for recipe-style writing

- Emphasis on cooking vocabulary
- Instruction-style sentence structure

**Analogy:** The model “speaks English” (from pre-training). You just taught it the “dialect” of recipe writing (fine-tuning).

## Fine-Tuning vs Pre-training From Scratch

Let’s compare your two models:

Metric	Chapter 2 (Scratch)	Chapter 3 (Fine-tuned)
Parameters	~10M	124M
Training data	1MB Shakespeare	200 recipe examples
Training time	~1 hour	~10 minutes
Starting loss	4.17	2.45
Final loss	~2.5	~1.7
Quality	Basic patterns	Professional-grade
Knowledge	Only training data	Billions of words

## Parameter Explanations

### Number of training epochs:

```
num_train_epochs=3
```

**What it means:** Read through your dataset 3 times.

- Chapter 2 needed 5,000+ steps because starting from random
- Chapter 3 only needs 3 epochs because already trained

### Learning rate:

```
learning_rate=5e-5
```

**What it means:** How much to adjust weights each step.

- $5e-5$  (0.00005) is LOWER than Chapter 2’s  $3e-4$

- **Why?** We're fine-tuning, not radically changing
- **Too high:** Forget pre-trained knowledge (“catastrophic forgetting”)
- **Too low:** Takes forever to adapt

**Temperature:**

```
temperature=0.8
```

**What it means:** Controls creativity (same as Chapter 2).

- **Higher (1.0+):** More creative, more random
- **Lower (0.5):** More predictable, conservative
- **0.8:** Good balance for recipes

**Batch size:**

```
per_device_train_batch_size=4
```

**What it means:** Process 4 examples at once.

- Same concept as Chapter 2's `batch_size`
- Lower value = less memory, slower training
- Higher value = more memory, faster training

## How the Model “Learns” During Fine-Tuning

**Step-by-step process:**

1. **Forward pass:** Model reads “Preheat oven to 350°F...”
2. **Prediction:** Tries to predict next word
3. **Error calculation:** Compares prediction to actual next word
4. **Backward pass:** Calculates how to adjust each weight
5. **Weight update:** Makes tiny adjustments (controlled by learning rate)
6. **Repeat:** Do this for all 200 examples, 3 times

**Key insight from Chapter 2:** This is exactly the same training loop you built! The only difference is starting from pre-trained weights instead of random.

## Why This Works With Small Data

**Question:** How can 200 examples teach a 124M parameter model anything?

**Answer:** It's not teaching from scratch—it's *adjusting* existing knowledge or weights.

**Analogy:**

- Training from scratch (Ch 2) = Teaching someone English who knows no language
- Fine-tuning (Ch 3) = Teaching an English speaker to write in journalistic style

The model already knows:

- Grammar and syntax
- Common words and phrases
- Sentence structure
- Context understanding

You only teach:

- Recipe-specific vocabulary emphasis
- Instructional tone
- Cooking-related patterns

## Limitations of This Quick Demo

Let's be honest about what this model **can't** do:

- ✗ Understand nutrition or food science
- ✗ Verify safe cooking temperatures
- ✗ Scale quantities correctly
- ✗ Reason about ingredient substitutions

**Why?** It learned patterns, not understanding.

**For production use**, you'd need:

- 1,000-10,000 examples (not 200)
- Validation data to test generalization
- Safety checks for temperatures/times
- Multiple training epochs with evaluation

**But for learning?** This demo perfectly illustrates the concept!

## What You Just Accomplished

Take a moment to appreciate what happened:

- ✓ Loaded a 124-million parameter neural network
- ✓ Fine-tuned it on custom data in 10 minutes
- ✓ Created a specialized recipe writer
- ✓ Compared results with the baseline
- ✓ All for \$0, with no prior AI experience needed

**Connection to Chapter 2:** You understand EXACTLY what happened under the hood because you built it yourself.

## Try It Yourself: Exercises

### Exercise 1: Change the Domain

Replace recipes with something you care about:

```
Example: Product descriptions
products = [
 "Premium cotton t-shirt. Soft, breathable fabric. Available in sizes S-XXL. Machine washable.",
 "Stainless steel water bottle. Keeps drinks cold for 24 hours. BPA-free. 32 oz capacity.",
 # ... add 18 more
] * 10
```

### Exercise 2: Adjust Temperature

Try different creativity levels:

```
More conservative (repetitive)
result = generate_recipe_instruction(prompt, temperature=0.5)

More creative (chaotic)
result = generate_recipe_instruction(prompt, temperature=1.2)
```

### Exercise 3: More Training Data

Add 30 more recipe examples. Does quality improve?

## Exercise 4: More Epochs

Change `num_train_epochs=3` to 5. Does the loss decrease more? Does output improve?

## Common Issues and Solutions

**Problem:** “CUDA out of memory”

**Solution:** Reduce `per_device_train_batch_size` from 4 to 2

**Problem:** Generated text is repetitive

**Solution:**

- Increase `no_repeat_ngram_size` from 2 to 3
- Increase temperature from 0.8 to 1.0

**Problem:** Generated text is nonsensical

**Solution:**

- Lower temperature from 0.8 to 0.6
- Add more training examples
- Train for more epochs

**Problem:** Model generates unrelated content

**Solution:** Need more training data (100+ examples minimum)

## Save Your Work

**To save your notebook:**

1. File □ Download □ Download .ipynb
2. Upload it back to Colab to resume later

**To save your model locally:**

```
from google.colab import files
Zip the model directory
!zip -r recipe-gpt2-final.zip ./recipe-gpt2-final
Download to your computer
files.download('recipe-gpt2-final.zip')
```

## Complete Code (All-in-One)

Here’s the entire fine-tuning process in one code block:

*# Complete Fine-Tuning Script*

```
!pip install transformers datasets accelerate -q
```

```
from transformers import GPT2LMHeadModel, GPT2Tokenizer
from transformers import Trainer, TrainingArguments
from transformers import DataCollatorForLanguageModeling
from datasets import Dataset
import torch
```

*# 1. Load model*

```
print("Loading GPT-2...")
tokenizer = GPT2Tokenizer.from_pretrained("gpt2")
model = GPT2LMHeadModel.from_pretrained("gpt2")
tokenizer.pad_token = tokenizer.eos_token
```

*# 2. Prepare data*

```
recipes = [
 "Preheat oven to 350°F. Mix flour, sugar, and eggs.",
 "Boil water. Add pasta and cook for 8-10 minutes.",
 "Heat olive oil in a skillet over medium heat. Add diced onions and cook until translucent. Add
 ↪ minced garlic and cook for 1 minute.",
 "Whisk eggs with milk and a pinch of salt. Pour into hot buttered pan. Scramble gently until just
 ↪ set.",
 "Combine ground beef with breadcrumbs, egg, and seasonings. Form into patties. Grill for 5 minutes
 ↪ per side.",
 "Slice vegetables into uniform pieces. Toss with oil and spices. Roast at 400°F for 20-25 minutes,
 ↪ stirring halfway.",
 "Melt butter in saucepan over low heat. Add flour and whisk constantly for 2 minutes. Gradually
 ↪ add milk while whisking.",
 "Season chicken breasts with salt and pepper. Heat oil in pan and cook 6-7 minutes per side until
 ↪ internal temperature reaches 165°F.",
 # ... add your examples
] * 10
```

```
dataset = Dataset.from_dict({"text": recipes})
tokenized = dataset.map(
 lambda x: tokenizer(x["text"], truncation=True,
 max_length=128, padding="max_length"),
 batched=True, remove_columns=["text"]
)
```

*# 3. Train*

```
print("Fine-tuning...")
trainer = Trainer(
 model=model,
 args=TrainingArguments(
 output_dir="./model",
 num_train_epochs=3,
 per_device_train_batch_size=4,
 save_steps=500,
 logging_steps=50,
 report_to="none"
),
 train_dataset=tokenized,
 data_collator=DataCollatorForLanguageModeling(
 tokenizer=tokenizer, mlm=False
),
```

```

)
trainer.train()

4. Test
print("\nTesting...")
model.to("cuda" if torch.cuda.is_available() else "cpu")

prompt = "Heat oil in a pan and"
inputs = tokenizer.encode(prompt, return_tensors="pt")
inputs = inputs.to(model.device)

outputs = model.generate(
 inputs,
 max_length=80,
 temperature=0.8,
 do_sample=True,
 no_repeat_ngram_size=2,
 pad_token_id=tokenizer.eos_token_id
)
print(f"\nPrompt: {prompt}")
print(f"Generated: {tokenizer.decode(outputs[0], skip_special_tokens=True)}")
print("\n✓ Done! Your model is fine-tuned.")

```

## What's Next: Your Learning Path

You've now experienced both extremes:

- **Chapter 2:** Built from scratch--slow but deep understanding
- **Chapter 3:** Fine-tuned quickly--fast but surface-level

Now you're ready for the deep dive.

## Part II: Training from Scratch–Deep Dive (Chapters 4-7)

Now that you've experienced fine-tuning, you'll learn how to train models from scratch properly:

### Chapter 4: Dataset Preparation

- Where to find quality training data
- Cleaning and preprocessing pipelines
- Tokenization strategies (word-level, subword, character)
- How much data you really need

### Chapter 5: Architecture Configuration

- Understanding GPT-2 architecture in depth

- Choosing model size (125M, 350M, 1B+ parameters)
- Configuring layers, attention heads, embedding dimensions
- Memory and compute requirements

## **Chapter 6: Training Loop & Monitoring**

- Setting up pretraining runs
- Learning rate schedules and optimization
- Using tools like TensorBoard and Weights & Biases
- When to stop training

## **Chapter 7: Evaluation & Benchmarks**

- Measuring model quality
- Perplexity and validation loss
- Downstream task evaluation
- Comparing with baselines

## **Part III: The MiniMind Case Study (Chapters 8-10)**

After mastering the fundamentals with GPT-2, you'll apply everything to train a complete modern SLM:

### **Chapter 8: Pretrain MiniMind**

- MiniMind architecture (26M-218M parameters)
- Training on Chinese text corpus
- Complete pretraining pipeline

### **Chapter 9: Supervised Fine-Tuning (SFT)**

- Instruction-following datasets
- Efficient fine-tuning
- When to use each technique

### **Chapter 10: Direct Preference Optimization (DPO)**

- Advanced alignment techniques
- Human preference learning
- Final model optimization

## **Why This Progression Matters**

Chapter 2: Build GPT **from scratch**

↓ (Understand architecture)

Chapter 3: Quick fine-tune GPT-2

↓ (Experience transfer learning)

Chapters 4-7: Deep dive **with** GPT-2

↓ (Master fundamentals)

Chapters 8-10: Complete MiniMind pipeline

↓ (Apply everything)

Chapters 11-12: Production deployment

**Complete Code Repository:** All code from this chapter is available at Google Colab:  
<https://rewriting.ai/bookcode/slm.php>

### Access codes:

1, 7KI6O3DXBC 2, 89JJRAHL36 3, T847N69BT8

4, HMNRT7QC9H 5, XD0ORK3619

**Next:** Chapter 4–Dataset Preparation: Where to find data, how to clean it, and how to prepare it for training ->

# Chapter 4: Dataset Preparation

## From Quick Experiments to Real-World Training

In Chapters 2 and 3, you got a taste of language model training:

- **Chapter 2:** Built GPT from scratch on 1MB of Shakespeare
- **Chapter 3:** Fine-tuned GPT-2 on 200 recipe examples in 30 minutes

Those were perfect for learning the concepts quickly. But now it's time to get serious.

### Welcome to Part II: Training from Scratch—Deep Dive

This is where you learn to work with real-world data at production scale. Not toy datasets, not quick experiments—actual training data that could power a commercial application. The kind of data preparation that takes 60-80% of a real ML project's time.

## Where This Fits in Your Learning Journey

**You are here:**

Part I: Foundations (Complete ✓)

- └ Chapter 1: Introduction ✓
- └ Chapter 2: Build GPT **from Scratch** ✓
- └ Chapter 3: Quick Start -- Fine-Tune GPT-2 ✓

Part II: Training **from Scratch** -- Deep Dive

- └ Chapter 4: Dataset Preparation ← YOU ARE HERE
- └ Chapter 5: Architecture Configuration (**next**)
- └ Chapter 6: Training Loop & Monitoring
- └ Chapter 7: Evaluation & Benchmarks

Coming later:

Part III: The MiniMind Case Study (Chapters 8-10)

Part IV: Production (Chapters 11-12)

### What Part II covers:

In the next four chapters, you'll master everything needed to train models from scratch:

- **Chapter 4 (this chapter):** Where to find real data and how to prepare it properly
- **Chapter 5:** How to configure model architecture (layers, dimensions, heads)

- **Chapter 6:** How to set up and monitor training runs
- **Chapter 7:** How to evaluate if your model is actually good

### Why this matters:

The quick experiments in Chapters 2-3 used convenient, clean datasets. Real projects aren't like that. You need to:

- Find or create your own training data
- Clean messy, real-world text
- Process gigabytes (not megabytes) of content
- Make architectural decisions for models 10-100x larger
- Train for hours or days (not minutes)

**After Part II**, you'll apply everything to the complete MiniMind case study in Part III, where you'll train a modern SLM through all three stages: Pretrain -> SFT -> DPO.

## Introduction: Data Is Everything

Here's the hard truth: **Data preparation takes 60-80% of a real machine learning project's time.** Not the exciting model architecture. Not hyperparameter tuning. Data preparation.

The quality of your data determines the quality of your model. A 350M parameter model trained on excellent data will outperform a 1B parameter model trained on garbage.

### What you'll learn:

- Where to find training data for any domain
- How to clean and format text properly
- Tokenization strategies and when to use each
- How much data you actually need (it's less than you think)
- Building a complete data pipeline from scratch

**What you'll build:** Three production-ready datasets for different use cases, plus a reusable data processing pipeline.

**Time required:** 2-3 hours

## Scaling Up: From Toy Data to Production Data

Let's reflect on what you've worked with so far: | Chapter | Dataset | Size | Purpose | |-----|-----|  
|---|-----| | Chapter 2 | Shakespeare | 1MB | Learn architecture | | Chapter 3 | 200 recipes | ~20KB |  
Experience fine-tuning | | **Chapter 4** | **Real-world** | **10MB-10GB** | **Production training** |

### The difference?

**Chapter 2-3 datasets:**

- Already clean and formatted
- Single domain, consistent style
- Small enough to process instantly
- Perfect for learning concepts

**Real-world datasets:**

- Messy, inconsistent, full of garbage
- Multiple sources and styles
- Too large to fit in memory
- Require careful processing pipelines

**This chapter teaches you to handle the real thing.**

## Part 1: Understanding Tokenization

Before collecting data, understand how it will be processed. Remember from Chapter 2:

```
Character-level tokenization (what you built)
text = "Hello world"
chars = sorted(list(set(text)))
stoi = {ch: i for i, ch in enumerate(chars)}
encode = lambda s: [stoi[c] for c in s]
```

This was simple but inefficient. Let’s understand the three main approaches used in production.

### The Three Tokenization Strategies

Strategy	Vocab Size	“Hello world”	Best For
Character	50-256	[H,e,l,l,o, ,w,o,r,l,d]	Small models, code
Word	50,000-100,000	[Hello, world]	Specific domains
Subword (BPE)	30,000-50,000	[Hello, world] or [Hel, lo, world]	General purpose

Note: the latest Deepseek OCR even uses an image of words as a token. see: <https://github.com/deepseek-ai/DeepSeek-OCR>

### Character-Level Tokenization

**What you built in Chapter 2.** Each character is a token.

```
Simple implementation
text = "Hello world"
chars = sorted(list(set(text))) # [' ', 'H', 'd', 'e', 'h', 'l', 'o', 'r', 'w']
vocab_size = len(chars) # 9 characters

stoi = {ch: i for i, ch in enumerate(chars)}
encoded = [stoi[c] for c in text] # [1, 3, 5, 5, 6, 0, 8, 6, 7, 5, 2]
```

**Pros:**

- Tiny vocabulary (256 for all ASCII)
- No unknown tokens ever
- Works with any text, including typos

**Cons:**

- Very long sequences (5-10x more tokens)
- Model must learn word boundaries from scratch
- Inefficient for large models

**Use when:**

- Model < 50M parameters (like Chapter 2's 10M model)
- Code generation (exact characters matter)
- Multiple languages with different scripts

**Word-Level Tokenization**

Each word is a token. Intuitive but problematic.

```
text = "Hello world! Hello again."
words = text.lower().split() # ['hello', 'world!', 'hello', 'again.']

vocab = sorted(set(words)) # Problem: 'world!' vs 'world'
vocab_size = len(vocab) # Grows indefinitely
```

**Pros:**

- Matches human understanding
- Shorter sequences
- Easy to interpret

**Cons:**

- Massive vocabulary (100,000+ for English)
- Can't handle unknown words (what if user says “supercalifragilisticexpialidocious”?)
- “run”, “runs”, “running” are all different tokens
- Punctuation creates duplicates (“world” vs “world!”)

#### Use when:

- Highly controlled domain (medical codes, legal terms)
- Small, fixed vocabulary (< 10,000 words)
- You rarely encounter new words

## Subword Tokenization (BPE) - The Modern Standard

**BPE** stands for **Byte Pair Encoding**.

**This is what GPT-2, GPT-3, BERT, and almost all modern models use.** It's a sweet spot between characters and words. Remember from Chapter 3? GPT-2 used BPE tokenization with 50,257 tokens.

#### How Byte Pair Encoding (BPE) works:

1. Start with characters
2. Find most common character pairs
3. Merge them into a new token
4. Repeat until you reach desired vocabulary size (usually 30,000-50,000)

#### Example training process:

```
Initial: character level
"low" → ['l', 'o', 'w']
"lower" → ['l', 'o', 'w', 'e', 'r']
"lowest" → ['l', 'o', 'w', 'e', 's', 't']

Iteration 1: 'l' + 'o' is common, merge to 'lo'
"low" → ['lo', 'w']
"lower" → ['lo', 'w', 'e', 'r']
"lowest" → ['lo', 'w', 'e', 's', 't']

Iteration 2: 'lo' + 'w' is common, merge to 'low'
"low" → ['low']
"lower" → ['low', 'e', 'r']
"lowest" → ['low', 'e', 's', 't']

Iteration 3: 'low' + 'e' is common, merge to 'lowe'
"lower" → ['lowe', 'r']
"lowest" → ['lowe', 's', 't']
```

**Result:** Common words become single tokens, rare words get broken into parts.

```
Real GPT-2 tokenization examples (from Chapter 3)
"Hello" -> [15496] # Common word: 1 token
"Supercalifragilisticexpialidocious" -> [12Supercalif, ragilistic, expial, idocious] # Rare:
→ multiple tokens
"unhappiness" -> [403, 71, 1324] # ['un', 'happiness'] or similar
```

**Pros:**

- Handles any text (no unknown tokens)
- Reasonable vocabulary size (30K-50K)
- Common words are efficient (1 token)
- Rare words degrade gracefully (split into parts)
- Same tokenizer works across languages

**Cons:**

- More complex to implement
- Tokens don't always align with words
- Must train tokenizer on your specific data

**Use when:** Almost always, especially for models > 100M parameters. This is what you'll use for GPT-2-like models in Chapters 4-7 and MiniMind in Chapters 8-10.

## Part 2: Practical Tokenization with Hugging Face

Let's implement all three approaches with real code, just like you used in Chapter 3.

### Setup

```
!pip install transformers datasets tokenizers -q

import torch
from transformers import GPT2Tokenizer, AutoTokenizer
from tokenizers import Tokenizer, models, trainers, pre_tokenizers
```

### Example 1: Using Pre-trained GPT-2 Tokenizer

```
Load GPT-2's tokenizer (what you used in Chapter 3)
tokenizer = GPT2Tokenizer.from_pretrained("gpt2")

Test it
text = "Hello world! This is a test of tokenization."
tokens = tokenizer.encode(text)
print(f"Text: {text}")
print(f"Tokens: {tokens}")
print(f"Number of tokens: {len(tokens)}")

Decode back
decoded = tokenizer.decode(tokens)
print(f"Decoded: {decoded}")

See actual token strings
token_strings = [tokenizer.decode([t]) for t in tokens]
print(f"Token strings: {token_strings}")
```

### Output:

```
Text: Hello world! This is a test of tokenization.
Tokens: [15496, 995, 0, 770, 318, 257, 1332, 286, 11241, 1634, 13]
Number of tokens: 11
Token strings: ['Hello', ' world', '!', ' This', ' is', ' a', ' test', ' of', ' token', ' ization', '.']
```

### Key observations:

- “Hello” is 1 token (common word)
- “ world” includes the space (GPT-2 uses byte-level BPE)
- “tokenization” split into “token” + “ization”
- 11 tokens for 9 words

**This is the same tokenizer you used in Chapter 3!** Now you understand what’s happening under the hood.

## Example 2: Training Your Own BPE Tokenizer

When should you train your own? When your domain has special vocabulary that GPT-2’s tokenizer doesn’t handle well.

```

from tokenizers import Tokenizer, models, trainers, pre_tokenizers, decoders

Example: Medical text with specialized terms
medical_texts = [
 "The patient presented with acute myocardial infarction.",
 "Administer 325mg aspirin and 5mg morphine sulfate IV.",
 "ECG shows ST-segment elevation in leads V1-V4.",
 "Troponin levels elevated to 15.2 ng/mL.",
 # ... add 1000+ more medical texts
]

Create a BPE tokenizer from scratch
tokenizer = Tokenizer(models.BPE())

Configure preprocessing
tokenizer.pre_tokenizer = pre_tokenizers.Whitespace()

Train on your domain data
trainer = trainers.BpeTrainer(
 vocab_size=10000, # Smaller vocab for specialized domain
 special_tokens=["<PAD>", "<UNK>", "<BOS>", "<EOS>"]
)

Train (in practice, use a file with lots of text)
tokenizer.train_from_iterator(medical_texts, trainer=trainer)

Test
text = "Patient shows ST-segment elevation myocardial infarction"
encoding = tokenizer.encode(text)
print(f"Tokens: {encoding.tokens}")
print(f"IDs: {encoding.ids}")

```

### When to train your own tokenizer:

- Medical/legal/scientific domains with unique terminology
- Non-English languages (you'll see this in the MiniMind case study - Chapter 8)
- Code (programming languages have different patterns)
- When you have > 10MB of domain text

### When to use pre-trained (GPT-2):

- General English text
- < 10MB of training data
- Quick prototyping
- Fine-tuning (Chapter 3 approach)

## Part 3: Where to Find Training Data

You need data. Lots of it. Here are your options for real-world, production-scale datasets.

## Getting Your Hugging Face Token and Saving It in Google Colab

Before using Hugging Face datasets or models, you need to log in with your personal access token.

### Step 1 – Create a Hugging Face Account

1. Go to <https://huggingface.co> and sign up (or log in if you already have an account).
2. In the top-right corner, click your **profile photo** -> **Settings** -> **Access Tokens**.
3. Click “**New token**”, give it a name (for example, colab), choose the “**Read**” role, and click **Create Token**.
4. Copy the generated token – it will look like this:

```
hf_A1B2C3D4E5F6G7H8I9J0...
```

### Step 2 – Store the Token Securely in Colab

In a Google Colab notebook:

1. Open the left-hand “ **Secrets**” tab (key icon).
2. Click “**+ Add new secret**”.
3. Enter:

- **Name:** HF\_TOKEN
- **Value:** (paste your Hugging Face token)

Now your token is stored securely in your Colab environment.

Note: of course if you run it on your local notebook, you need to save the HF\_TOKEN in your local MAC/PC environment.

### Step 3 – Use the Token in Code

Access it in Python like this:

```
import os
from huggingface_hub import login

login(token=os.environ["HF_TOKEN"])
```

## Option 1: Public Datasets

### Wikipedia

**What:** Free, high-quality encyclopedia articles in 300+ languages.

**Size:** ~20GB (English), 6M+ articles

**Quality:** High - well-written, factual

#### How to download:

First, let's start with a smaller dataset to understand the structure:

```
Load a smaller dataset for demo
from datasets import load_dataset
print("Downloading SQuAD dataset...")
dataset = load_dataset("squad", split='train[:1000]') # Load only the first 1000 examples

print(f"Total examples: {len(dataset):,}")
print(f"\nFirst example:")
print(dataset[0]['title'])
print(dataset[0]['context'][:500])
print(dataset[0]['question'])
print(dataset[0]['answers'])
```

Output:

Downloading SQuAD dataset...

Total examples: 1,000

First example:

University\_of\_Notre\_Dame

Architecturally, the school has a Catholic character. Atop the Main Building's gold dome is a golden  
↪ statue of the Virgin Mary...

To whom did the Virgin Mary allegedly appear in 1858 in Lourdes France?

```
{'text': ['Saint Bernadette Soubirous'], 'answer_start': [515]}
```

**Scaling up:** When you're ready for full-scale training (Chapters 6-7), you can download the complete Wikipedia:

```
Takes 20-30 minutes and ~20GB storage
from datasets import load_dataset

print("Downloading English Wikipedia...")
dataset = load_dataset("wikimedia/wikipedia", "20231101.en")

print(f"Total articles: {len(dataset['train']):,}")
print("\nFirst article:")
print(dataset['train'][0]['title'])
print(dataset['train'][0]['text'][:500])
```

**Good for:**

- General knowledge models
- Question answering
- Summarization

**Not good for:**

- Current events (frozen at download date)
- Specialized domains (too general)
- Conversational tone (too formal)

**Common Crawl**

**What:** Raw web scrapes. Billions of web pages.

**Size:** Petabytes (yes, really)

**Quality:** Mixed. Contains gold and garbage.

**How to use:**

```
Don't download raw Common Crawl!
Use pre-filtered versions like C4 or OSCAR

from datasets import load_dataset

English C4, streamed (no full download)
ds = load_dataset("allenai/c4", "en", streaming=True)

Peek at a few samples
for i, ex in enumerate(ds["train"].take(5), 1):
 print(f"\n{' '*50}\nSample {i}\n")
 print(ex["text"][:300])
```

**C4 Dataset Structure:** Each sample has:

- **text**: The actual text content
- **url**: Source URL where text was scraped from
- **timestamp**: When it was crawled

### Different C4 Versions:

```
1. Standard C4 (cleaned)
dataset = load_dataset("allenai/c4", "en", split="train", streaming=True)

2. C4 without cleaning
dataset = load_dataset("allenai/c4", "en.noclean", split="train", streaming=True)

3. RealNews-like subset (higher quality)
dataset = load_dataset("allenai/c4", "realnewslike", split="train", streaming=True)

4. Validation split
dataset = load_dataset("allenai/c4", "en", split="validation", streaming=True)
```

### Good for:

- Training very large models (> 1B parameters)
- Diverse language patterns
- When you need massive scale

### Not good for:

- Quality-sensitive applications
- Specialized domains
- If you have < 100GB free disk space

### Books Corpus

**What:** 11,000 unpublished books, fiction and non-fiction.

**Size:** ~5GB

**Quality:** High (actual books)

**Status:** Restricted due to copyright concerns

**Alternative:** Use openly licensed books from Project Gutenberg.

```
Project Gutenberg example
!wget https://www.gutenberg.org/files/1342/1342-0.txt # Pride and Prejudice

with open('1342-0.txt', 'r', encoding='utf-8') as f:
 book = f.read()

print(f"Length: {len(book):,} characters")
print(book[:500])
```

## Option 2: Domain-Specific Sources

### Academic Papers (ArXiv, PubMed)

#### ArXiv Dataset:

```
from datasets import load_dataset

ArXiv papers in parquet format
dataset = load_dataset(
 "ccdv/arxiv-summarization",
 split="train",
 streaming=True
)

arxiv_texts = []
for i, item in enumerate(dataset):
 if i >= 5000:
 break
 # Has 'article' and 'abstract' fields
 arxiv_texts.append(item['article'])

 if i % 1000 == 0:
 print(f"Processed {i} papers...")

print(f"✅ Collected {len(arxiv_texts)} ArXiv papers")
```

#### Alternative approach:

```

from datasets import load_dataset

ArXiv with abstracts and summaries
dataset = load_dataset("ccdv/arxiv-summarization", split="train[:5000]")

print(f"Loaded {len(dataset)} papers")
print(f"Fields: {dataset[0].keys()}")

Extract texts
arxiv_texts = [item['article'] for item in dataset]
abstracts = [item['abstract'] for item in dataset]

```

### PubMed Dataset:

```

from datasets import load_dataset

PubMed abstracts
dataset = load_dataset(
 "ccdv/pubmed-summarization",
 split="train",
 streaming=True
)

pubmed_texts = []
for i, item in enumerate(dataset):
 if i >= 5000:
 break
 pubmed_texts.append(item['article'])

print(f"✅ Collected {len(pubmed_texts)} PubMed papers")

```

### Or using Parquet directly:

```

from datasets import load_dataset

Bypass via universal Parquet loader
ds = load_dataset(
 "parquet",
 data_files="hf://datasets/ccdv/pubmed-summarization/**/*.parquet",
 split="train[:5000]"
)
print(ds[0]["article"][:200])

```

### Legal Documents

```

from datasets import load_dataset

US Congressional bills
dataset = load_dataset("billsum", split="train")

print(f"✅ Loaded {len(dataset)} legislative bills")

Extract bill texts
bills = [item['text'] for item in dataset]
summaries = [item['summary'] for item in dataset]

print(f"Sample bill: {bills[0][:300]}...")

```

### Alternative legal datasets:

```

from datasets import load_dataset

Option 1: EUR-Lex case classification
dataset1 = load_dataset("lex_glue", "eurlex", split="train")

Option 2: SCOTUS case classification
dataset2 = load_dataset("lex_glue", "scotus", split="train")

Option 3: Legal contracts (LEDGAR)
dataset3 = load_dataset("lex_glue", "ledgar", split="train")

Option 4: UNFAIR-ToS (Terms of Service)
dataset4 = load_dataset("lex_glue", "unfair_tos", split="train")

print(f"EUR-Lex: {len(dataset1)} docs")
print(f"SCOTUS: {len(dataset2)} docs")
print(f"LEDGAR: {len(dataset3)} docs")
print(f"Unfair ToS: {len(dataset4)} docs")

Extract texts
eurlex_texts = [item['text'] for item in dataset1]

```

### Code Repositories

```

from datasets import load_dataset

The File contains GitHub code
dataset = load_dataset(
 "monology/pile-uncopyrighted",
 split="train",
 streaming=True
)

Filter for code (GitHub subset)
code_samples = []
for i, item in enumerate(dataset):
 if i >= 50000: # Check more samples
 break

 # Check if it's from GitHub
 if item.get('meta', {}).get('pile_set_name') == 'Github':
 code_samples.append(item['text'])

 if len(code_samples) <= 3:
 print(f"\n{'='*50}")
 print(f"Sample {len(code_samples)}:")
 print(item['text'][:300])

 if len(code_samples) >= 1000:
 break

 if i % 5000 == 0:
 print(f"Checked {i} samples, found {len(code_samples)} code files...")

print(f"\n✅ Found {len(code_samples)} code samples")

```

## Option 3: Your Own Data

### Best option when:

- You have proprietary data
- You need maximum relevance
- Privacy is critical (remember Chapter 1's HIPAA example?)

### Sources:

- Company documents
- Customer support logs
- Internal emails (with permission!)
- Research notes
- Product descriptions
- Your own writing

### Example: Scraping your company's documentation

```

import requests
from bs4 import BeautifulSoup

def scrape_docs(url):
 """Scrape text from documentation pages"""
 response = requests.get(url)
 soup = BeautifulSoup(response.content, 'html.parser')

 # Remove navigation, headers, footers
 for element in soup(['nav', 'header', 'footer', 'script', 'style']):
 element.decompose()

 # Extract text
 text = soup.get_text(separator='\n', strip=True)
 return text

Example usage
docs_url = "https://your-company.com/docs"
text = scrape_docs(docs_url)
print(f"Extracted {len(text):,} characters")
print(text[:500])

```

## How Much Data Do You Need?

This is the most common question. The answer: **It depends on your model size and task.**

**Rule of thumb for training from scratch:**

Model Size	Minimum Data	Comfortable Amount	Examples
125M params	10MB (10M chars)	100MB+	5,000 documents
350M params	50MB	500MB+	25,000 documents
1B params	200MB	2GB+	100,000 documents
3B params	1GB	10GB+	500,000 documents

**For fine-tuning (Chapter 3 style):** You can get away with much less:

- 100 examples minimum (what you did with recipes)
- 1,000 examples comfortable
- 10,000+ examples ideal

**Why the difference?**

- **Training from scratch (what you'll do in Chapters 5-7):** Model learns everything (language, facts, patterns)
- **Fine-tuning (what you did in Chapter 3):** Model only adapts existing knowledge

**For the MiniMind case study (Chapters 8-10):** You'll work with multi-gigabyte Chinese/English text corpora for pretraining, then smaller datasets for SFT and DPO.

## Part 4: Cleaning and Formatting Data

Raw data is messy. Much messier than the clean Shakespeare text from Chapter 2 or the formatted recipes from Chapter 3. Here's how to handle real-world data.

### Common Issues and Fixes

```
import re
from typing import List

class TextCleaner:
 """Production-quality text cleaning pipeline"""

 @staticmethod
 def remove_urls(text: str) -> str:
 """Remove URLs"""
 return re.sub(r'http\S+|www.\S+', '', text)

 @staticmethod
 def remove_html(text: str) -> str:
 """Remove HTML tags"""
 return re.sub(r'<[^>]+>', '', text)

 @staticmethod
 def normalize_whitespace(text: str) -> str:
 """Normalize whitespace"""
 # Replace multiple spaces/newlines with single ones
 text = re.sub(r'\s+', ' ', text)
 return text.strip()

 @staticmethod
 def remove_short_lines(text: str, min_length: int = 50) -> str:
 """Remove lines shorter than min_length characters"""
 lines = text.split('\n')
 lines = [line for line in lines if len(line.strip()) >= min_length]
 return '\n'.join(lines)

 @staticmethod
 def remove_duplicates(texts: List[str]) -> List[str]:
 """Remove exact duplicate documents"""
 seen = set()
 unique = []
 for text in texts:
 if text not in seen:
 seen.add(text)
 unique.append(text)
 return unique

 @classmethod
 def clean(cls, text: str) -> str:
 """Apply all cleaning steps"""
 text = cls.remove_urls(text)
 text = cls.remove_html(text)
```

```

 text = cls.normalize_whitespace(text)
 return text

Example usage
dirty_text = """
<html><body>
Check out https://example.com for more info!

This is a test with extra spaces.

And too many blank lines.
</body></html>
"""

clean_text = TextCleaner.clean(dirty_text)
print("BEFORE:")
print(dirty_text)
print("\nAFTER:")
print(clean_text)

```

## Deduplication: Critical for Quality

### Why deduplicate?

- Prevents memorization of repeated content
- Reduces overfitting
- Makes training more efficient
- Improves generalization

### Three levels of deduplication:

#### 1. Exact Deduplication (Easy)

```

def exact_deduplicate(texts: List[str]) -> List[str]:
 """Remove exact duplicates"""
 return list(dict.fromkeys(texts)) # Preserves order

Example
texts = ["Hello world", "Goodbye", "Hello world", "Hi there"]
unique = exact_deduplicate(texts)
print(f"Original: {len(texts)}, Unique: {len(unique)}")

```

#### 2. Near-Duplicate Detection (Medium)

```

from difflib import SequenceMatcher

def similarity(text1: str, text2: str) → float:
 """Calculate similarity between two texts"""
 return SequenceMatcher(None, text1, text2).ratio()

def fuzzy_deduplicate(texts: List[str], threshold: float = 0.9) → List[str]:
 """Remove near-duplicates"""
 unique = []
 for text in texts:
 is_duplicate = False
 for existing in unique:
 if similarity(text, existing) > threshold:
 is_duplicate = True
 break
 if not is_duplicate:
 unique.append(text)
 return unique

Example
texts = [
 "The quick brown fox jumps over the lazy dog.",
 "The quick brown fox jumps over the lazy dog!", # Very similar
 "A completely different sentence here.",
]
unique = fuzzy_deduplicate(texts, threshold=0.9)
print(f"Removed {len(texts) - len(unique)} near-duplicates")

```

### 3. MinHash LSH (Advanced, for large datasets)

```

For datasets > 100K documents
!pip install datasketch -q

from datasketch import MinHash, MinHashLSH

def create_minhash(text: str, num_perm: int = 128) → MinHash:
 """Create MinHash signature"""
 mh = MinHash(num_perm=num_perm)
 for word in text.lower().split():
 mh.update(word.encode('utf8'))
 return mh

def minhash_deduplicate(texts: List[str], threshold: float = 0.9) → List[str]:
 """Fast near-duplicate detection using MinHash LSH"""
 lsh = MinHashLSH(threshold=threshold, num_perm=128)

 # Index all documents
 signatures = {}
 for i, text in enumerate(texts):
 mh = create_minhash(text)
 signatures[i] = mh
 lsh.insert(i, mh)

```

```

Find duplicates
duplicates = set()
for i in range(len(texts)):
 results = lsh.query(signatures[i])
 if len(results) > 1: # Found duplicates
 # Keep only the first occurrence
 duplicates.update(results[1:])

Return only non-duplicates
return [text for i, text in enumerate(texts) if i not in duplicates]

This is MUCH faster for large datasets

```

**You'll use these deduplication techniques extensively in Chapters 6-7 when training larger models.**

## Formatting for Training

Models expect data in specific formats. Here are the three most common:

### Format 1: Plain Text (Simplest)

```

Just concatenate documents with separators
def format_plain_text(documents: List[str]) -> str:
 """Simple concatenation with document separator"""
 separator = "\n\n### END OF DOCUMENT ###\n\n"
 return separator.join(documents)

docs = [
 "First document text here.",
 "Second document text here.",
 "Third document text here.",
]

formatted = format_plain_text(docs)
print(formatted)

```

### Format 2: JSONL (Most Common)

```
import json

def save_as_jsonl(documents: List[str], filename: str):
 """Save as JSON Lines format (one JSON object per line)"""
 with open(filename, 'w') as f:
 for doc in documents:
 json.dump({"text": doc}, f)
 f.write('\n')

Save
save_as_jsonl(docs, "training_data.jsonl")

Load
def load_jsonl(filename: str) -> List[str]:
 """Load from JSONL"""
 texts = []
 with open(filename, 'r') as f:
 for line in f:
 data = json.loads(line)
 texts.append(data['text'])
 return texts
```

### Format 3: Tokenized Tensor (Fastest)

```
import torch
from transformers import GPT2Tokenizer

def create_tokenized_dataset(
 texts: List[str],
 tokenizer,
 max_length: int = 512,
 output_file: str = "tokenized_data.pt"
):
 """Pre-tokenize and save as PyTorch tensor"""
 all_tokens = []

 for text in texts:
 tokens = tokenizer.encode(text, max_length=max_length, truncation=True)
 all_tokens.extend(tokens)

 # Save as tensor
 tensor = torch.tensor(all_tokens, dtype=torch.long)
 torch.save(tensor, output_file)

 print(f"Saved {len(all_tokens):,} tokens to {output_file}")
 return tensor

Usage
tokenizer = GPT2Tokenizer.from_pretrained("gpt2")
tensor = create_tokenized_dataset(docs, tokenizer)
```

**You'll use Format 3 (tokenized tensors) in Chapters 6-7 for efficient training.**

## Part 5: Complete Data Pipeline

Let's build a production-ready pipeline that does everything. This is the kind of pipeline you'll use in Chapters 6-7 for training and in Chapters 8-10 for MiniMind.

```
import os
import json
from typing import List, Dict
from datasets import load_dataset
from transformers import GPT2Tokenizer
import torch

class DataPipeline:
 """Complete data preparation pipeline"""

 def __init__(self, tokenizer_name: str = "gpt2"):
 self.tokenizer = GPT2Tokenizer.from_pretrained(tokenizer_name)
 self.cleaner = TextCleaner()

 def load_from_source(self, source: str, limit: int = None) → List[str]:
 """Load data from various sources"""
 if source == "wikipedia":
 dataset = load_dataset("wikimedia/wikipedia", "20231101.en", split="train")
 texts = [item['text'] for item in dataset]
 elif source.endswith('.jsonl'):
 texts = self.load_jsonl(source)
 elif source.endswith('.txt'):
 with open(source, 'r') as f:
 text = f.read()
 texts = [text] # Single document
 else:
 raise ValueError(f"Unknown source: {source}")

 if limit:
 texts = texts[:limit]

 return texts

 def process(
 self,
 texts: List[str],
 min_length: int = 100,
 max_length: int = 512,
 deduplicate: bool = True
) → Dict:
 """Complete processing pipeline"""
 print(f"Starting with {len(texts):,} documents")

 # 1. Clean
 print("Cleaning...")
 texts = [self.cleaner.clean(text) for text in texts]

 # 2. Filter short documents
 print(f"Filtering documents shorter than {min_length} characters...")
```

```

texts = [t for t in texts if len(t) >= min_length]
print(f" Remaining: {len(texts):,}")

3. Deduplicate
if deduplicate:
 print("Deduplicating...")
 original_count = len(texts)
 texts = list(dict.fromkeys(texts))
 print(f" Removed {original_count - len(texts):,} duplicates")

4. Tokenize
print("Tokenizing...")
all_tokens = []
for text in texts:
 tokens = self.tokenizer.encode(
 text,
 max_length=max_length,
 truncation=True
)
 all_tokens.extend(tokens)
 all_tokens.append(self.tokenizer.eos_token_id) # Add separator

print(f"Total tokens: {len(all_tokens):,}")

5. Split train/val
split_idx = int(0.9 * len(all_tokens))
train_tokens = all_tokens[:split_idx]
val_tokens = all_tokens[split_idx:]

return {
 'train': torch.tensor(train_tokens, dtype=torch.long),
 'val': torch.tensor(val_tokens, dtype=torch.long),
 'num_documents': len(texts),
 'num_tokens': len(all_tokens),
 'vocab_size': len(self.tokenizer),
}

def save(self, data: Dict, output_dir: str):
 """Save processed data"""
 os.makedirs(output_dir, exist_ok=True)

 torch.save(data['train'], f"{output_dir}/train.pt")
 torch.save(data['val'], f"{output_dir}/val.pt")

Save metadata
metadata = {
 'num_documents': data['num_documents'],
 'num_tokens': data['num_tokens'],
 'vocab_size': data['vocab_size'],
}
with open(f"{output_dir}/metadata.json", 'w') as f:
 json.dump(metadata, f, indent=2)

print(f"Saved to {output_dir}/")

@staticmethod
def load_jsonl(filename: str) -> List[str]:

```

```

"""Load JSONL file"""
texts = []
with open(filename, 'r') as f:
 for line in f:
 data = json.loads(line)
 texts.append(data['text'])
 return texts

Example usage: Process sample data
pipeline = DataPipeline()

Load sample data
texts = [
 "This is the first document about machine learning and neural networks.",
 "This is the second document about deep learning and transformer architectures.",
 "The third document discusses natural language processing and tokenization.",
 # In practice, load thousands of documents
]

Process
data = pipeline.process(
 texts,
 min_length=20,
 max_length=512,
 deduplicate=True
)

Save
pipeline.save(data, "./processed_data")

print("\nDataset ready for training!")
print(f"Training tokens: {len(data['train']):,}")
print(f"Validation tokens: {len(data['val']):,}")

```

**This pipeline is what you'll use:**

- In Chapters 6-7: For training GPT-2-like models from scratch
- In Chapter 8: For pretraining MiniMind (with Chinese tokenizer)
- In Chapters 9-10: For preparing SFT and DPO datasets

## Part 6: Real Examples - Three Complete Datasets

Let's prepare three real-world datasets you could actually use for training.

First, install the correct version:

```
!pip install "datasets<3.0"
```

Then restart your session and grant access to HF\_TOKEN.

## Example 1: Medical Q&A Dataset

```
Medical literature from PubMed
from datasets import load_dataset

Using Parquet loader for reliability
ds = load_dataset(
 "parquet",
 data_files="hf://datasets/ccdv/pubmed-summarization/**/*.parquet",
 split="train[:5000]"
)

Extract texts
medical_texts = [item['article'] for item in ds if item.get('article')]

print(f"Loaded {len(medical_texts)} medical abstracts")
print(f"Example: {medical_texts[0][:200]}...")

Process
pipeline = DataPipeline()
data = pipeline.process(medical_texts, min_length=100, max_length=512)
pipeline.save(data, "./medical_dataset")
```

**You could use this dataset in Chapter 6-7 to train a medical domain model.**

## Example 2: Code Dataset (Python)

```
Python code from GitHub
from datasets import load_dataset

CodeParrot's curated Python dataset
dataset = load_dataset(
 "codeparrot/codeparrot-clean",
 split="train",
 streaming=True
)

code_texts = []
for i, item in enumerate(dataset):
 if i >= 10000:
 break
 code_texts.append(item['content'])

print(f"Collected {len(code_texts)} Python files")

Process
pipeline = DataPipeline()
data = pipeline.process(code_texts, min_length=200, max_length=1024)
pipeline.save(data, "./python_dataset")
```

**This could be used in Chapters 6-7 for a code generation model.**

### Example 3: Custom Domain (Your Company Docs)

```
Scrape your documentation
import requests
from bs4 import BeautifulSoup

def scrape_documentation(base_url: str, max_pages: int = 100) → List[str]:
 """Scrape documentation pages"""
 texts = []
 visited = set()
 to_visit = [base_url]

 while to_visit and len(texts) < max_pages:
 url = to_visit.pop(0)
 if url in visited:
 continue

 try:
 response = requests.get(url, timeout=10)
 soup = BeautifulSoup(response.content, 'html.parser')

 # Extract text
 for element in soup(['nav', 'header', 'footer', 'script']):
 element.decompose()
 text = soup.get_text(separator='\n', strip=True)
 texts.append(text)
 visited.add(url)

 # Find more links
 for link in soup.find_all('a', href=True):
 full_url = requests.compat.urljoin(base_url, link['href'])
 if full_url.startswith(base_url) and full_url not in visited:
 to_visit.append(full_url)

 except Exception as e:
 print(f"Error scraping {url}: {e}")
 continue

 return texts

Example usage
docs = scrape_documentation("https://your-company.com/docs", max_pages=50)

Process
pipeline = DataPipeline()
data = pipeline.process(docs, min_length=100, max_length=512)
pipeline.save(data, "./company_docs_dataset")
```

Perfect for Chapter 3-style fine-tuning or Chapter 6-7 training on proprietary data.

## Part 7: Quality Checks

Before training, verify your data quality. This is critical!

```
def analyze_dataset(data: Dict, tokenizer):
 """Analyze processed dataset quality"""
 train_tokens = data['train'].tolist()

 # Basic stats
 print("Dataset Statistics")
 print("=" * 50)
 print(f"Total training tokens: {len(train_tokens):,}")
 print(f"Vocabulary size: {data['vocab_size']:,}")
 print(f"Documents: {data['num_documents']:,}")

 # Token distribution
 unique_tokens = len(set(train_tokens))
 print(f"\nUnique tokens used: {unique_tokens:,} ({unique_tokens/data['vocab_size']*100:.1f}% of
 ↪ vocab)")

 # Sample sequences
 print("\nSample sequences:")
 for i in range(0, min(3000, len(train_tokens)), 1000):
 sequence = train_tokens[i:i+50]
 text = tokenizer.decode(sequence)
 print(f"\n[Position {i:,}]")
 print(text[:200])

 # Check for issues
 print("\nQuality Checks:")

 # 1. Repetition check
 def has_repetition(tokens, window=10):
 for i in range(len(tokens) - window * 2):
 if tokens[i:i+window] == tokens[i+window:i+window*2]:
 return True
 return False

 sample = train_tokens[:10000]
 if has_repetition(sample):
 print("⚠ Warning: Detected repetitive patterns")
 else:
 print("✓ No obvious repetitive patterns")

 # 2. Diversity check
 diversity = unique_tokens / len(train_tokens[:10000])
 print(f"✓ Token diversity: {diversity:.3f} (higher is better)")

 # 3. Length check
 avg_tokens_per_doc = len(train_tokens) / data['num_documents']
 print(f"✓ Average tokens per document: {avg_tokens_per_doc:.1f}")

 # Run analysis
 analyze_dataset(data, pipeline.tokenizer)
```

You'll run quality checks like these before every training run in Chapters 6-7.

## Part 8: Common Issues and Solutions

### Issue 1: Dataset Too Large for Memory

**Problem:** Can't load 50GB Wikipedia into RAM.

**Solution:** Use streaming or chunking.

```
import os
import torch
from datasets import load_dataset
from transformers import AutoTokenizer

Create output directory
os.makedirs("./chunks", exist_ok=True)

Initialize tokenizer
tokenizer = AutoTokenizer.from_pretrained("gpt2")

Use current Wikipedia dataset with streaming
dataset = load_dataset(
 "wikimedia/wikipedia",
 "20231101.en",
 split="train",
 streaming=True
)

def process_streaming(dataset, chunk_size=1000, total_chunks=10):
 all_tokens = []
 chunk_num = 0

 for i, item in enumerate(dataset):
 if i >= chunk_size * total_chunks:
 break

 # Extract text
 text = item['text']

 # Tokenize
 tokens = tokenizer.encode(text, max_length=512, truncation=True)
 all_tokens.extend(tokens)

 # Save periodically
 if (i + 1) % chunk_size == 0:
 chunk_num = (i + 1) // chunk_size
 torch.save(
 torch.tensor(all_tokens),
 f"./chunks/chunk_{chunk_num}.pt"
)
 print(f"Saved chunk {chunk_num} with {len(all_tokens):,} tokens")
```

```

 all_tokens = [] # Clear memory

 # Save final chunk if there are remaining tokens
 if all_tokens:
 chunk_num += 1
 torch.save(
 torch.tensor(all_tokens),
 f"./chunks/chunk_{chunk_num}.pt"
)
 print(f"Saved final chunk {chunk_num} with {len(all_tokens):,} tokens")

 return True

Process the data
process_streaming(dataset)
print("✅ Processing complete!")

```

**You'll use streaming in Chapter 6 when training on large datasets.**

## Issue 2: Unbalanced Dataset

**Problem:** 90% of data is one category, 10% another.

**Solution:** Oversample minority or undersample majority.

```

def balance_dataset(texts: List[str], labels: List[int]) -> tuple:
 """Balance dataset by oversampling minority class"""
 from collections import Counter
 import random

 # Count labels
 counts = Counter(labels)
 max_count = max(counts.values())

 # Oversample
 balanced_texts = []
 balanced_labels = []

 for label in set(labels):
 label_texts = [t for t, l in zip(texts, labels) if l == label]

 # Repeat until reaching max_count
 while len(label_texts) < max_count:
 label_texts.extend(random.sample(label_texts, min(len(label_texts), max_count -
 len(label_texts))))

 balanced_texts.extend(label_texts[:max_count])
 balanced_labels.extend([label] * max_count)

 return balanced_texts, balanced_labels

```

### Issue 3: Non-English or Mixed Language

**Problem:** Training on multiple languages or non-Latin scripts.

**Solution:** Use multilingual tokenizer or train your own.

```
Use multilingual BERT tokenizer
from transformers import BertTokenizer

tokenizer = BertTokenizer.from_pretrained('bert-base-multilingual-cased')

Test with multiple languages
texts = [
 "Hello world", # English
 "Bonjour le monde", # French
 "こんにちは", # Japanese
 "بالعالم مرحبا", # Arabic
]

for text in texts:
 tokens = tokenizer.encode(text)
 print(f"{text} → {len(tokens)} tokens")
```

Output:

```
Hello world → 4 tokens
Bonjour le monde → 7 tokens
こんにちは → 9 tokens
بالعالم مرحبا → 9 tokens
```

You'll see this in action in Chapter 8 when training MiniMind on Chinese text!

## Summary and Best Practices

### Data Preparation Checklist

Before starting training in Chapters 5-7:

- ☐ **Source selected:** Wikipedia, Common Crawl, domain-specific, or custom
- ☐ **Minimum amount:** 10MB for 125M model, 100MB for 350M, 1GB for 1B
- ☐ **Cleaned:** URLs, HTML, extra whitespace removed
- ☐ **Deduplicated:** Exact or near-duplicate detection
- ☐ **Formatted:** Plain text, JSONL, or pre-tokenized
- ☐ **Tokenizer chosen:** Character-level, word-level, or BPE
- ☐ **Split:** 90% training, 10% validation
- ☐ **Quality checked:** Diversity, length, patterns verified

## Best Practices

1. **Start small:** Test pipeline on 1,000 documents before processing millions
2. **Save intermediate results:** Don't reprocess from scratch if something fails
3. **Monitor quality:** Check samples at each step
4. **Version your data:** Keep track of cleaning/filtering parameters
5. **Document decisions:** Note why you chose certain thresholds

## What's Next: The Path Forward

You've now mastered data preparation--the foundation of everything that follows.

## Coming in Part II:

### Chapter 5: Architecture Configuration

- How to choose model size (125M? 350M? 1B?)
- Configuring layers, heads, embedding dimensions
- Understanding GPT-2 architecture in depth
- Memory and compute requirements

### Chapter 6: Training Loop & Monitoring

- Setting up pretraining runs
- Learning rate schedules and optimization
- Using TensorBoard and Weights & Biases
- When to stop training

### Chapter 7: Evaluation & Benchmarks

- Measuring model quality
- Perplexity and validation loss
- Downstream task evaluation
- Comparing with baselines

## Key Takeaways

- **Tokenization matters:** BPE for most cases, characters for small models or code
- **Data sources:** Wikipedia (general), Common Crawl (massive), domain-specific (focused)
- **Clean religiously:** Remove HTML, URLs, duplicates
- **Size requirements:** 10MB minimum per 125M parameters for training from scratch
- **Pipeline everything:** Automate cleaning, deduplication, formatting
- **Quality over quantity:** 1GB of clean data beats 10GB of garbage
- **Scale awareness:** Toy datasets (Chapters 2-3) vs production datasets (Chapters 4-7)
- **Real-world skills:** You now have production-quality data preparation skills

**The foundation is set.** You understand data at a level most practitioners never reach. Now you're ready to make intelligent decisions about model architecture.

**Complete Code Repository:** All code from this chapter is available at Google Colab: <https://rewriting.ai/bookcode/slm.php>

### Access codes:

**Next:** Chapter 5–Model Architecture & Configuration: How to design your GPT-2-like model ->

# Chapter 5: Model Architecture & Configuration

## From Understanding to Design

You've built a small GPT from scratch (Chapter 2), fine-tuned GPT-2 quickly (Chapter 3), and prepared real-world data (Chapter 4). Now comes a critical question: **What size model should you actually build?**

The internet is full of stories about GPT-3's 175 billion parameters or GPT-4's trillion parameters. But here's what they don't tell you: **most real-world problems don't need that scale.**

A well-configured 350M parameter model can outperform a poorly configured 1B model. This chapter teaches you how to make those architectural decisions intelligently.

## Where This Fits in Your Learning Journey

**What you've learned so far:**

- **Chapter 2:** Built a 10M parameter model to understand transformer architecture
- **Chapter 3:** Fine-tuned GPT-2's 125M parameters in 30 minutes
- **Chapter 4:** Prepared production-scale datasets (10MB-10GB)

**What this chapter teaches:**

Now it's time to design your own model from first principles. You'll learn:

- How to scale from 10M -> 125M -> 350M -> 1B+ parameters
- Why GPT-2 uses 768 dimensions and 12 layers (not random choices!)
- How to configure models for different use cases
- The principles that apply to GPT-2, MiniMind, and modern SLMs

**After this chapter:**

- **Chapter 6:** You'll train these configured models
- **Chapter 7:** You'll evaluate if they work well
- **Chapters 8-10:** You'll apply everything to MiniMind (26M-218M params)

## Introduction: Size Matters (But Not How You Think)

Remember Chapter 2? You built a ~10M parameter model. It “worked”, but it was tiny and not really useful.

Chapter 3? You used GPT-2’s 125M parameters. Much better results, much faster.

But **why** 125M? Why 768 dimensions? Why 12 layers? These aren’t arbitrary—they’re carefully chosen based on proven architectural principles.

**What you’ll learn:**

- How model size relates to task complexity
- The relationship between parameters, layers, and hidden dimensions
- How to choose attention heads and context length
- A decision framework for your specific use case
- Configuration templates for common scenarios

**What you’ll build:** Three different model configurations optimized for different tasks, ready to train in Chapter 6.

**Time required:** 1-2 hours

## Reflecting on What You’ve Built

Let’s compare the models you’ve worked with:

Chapter	Model	Parameters	Architecture	Training Time
Chapter 2	Custom GPT	~10M	4 layers, 64 dim, 4 heads	1 hour
Chapter 3	GPT-2	125M	12 layers, 768 dim, 12 heads	Pre-trained
Chapter 5	Your design	50M-1B	You decide	Chapter 6

**The principles you learned in Chapter 2 scale to any size.** The 10M model and GPT-2’s 125M model use identical architecture—just different dimensions!

## Part 1: Understanding Parameters

Remember from Chapter 2 when you built GPT? The model had **parameters**—weights and biases that get adjusted during training. Let’s understand how parameters scale.

**What Counts as a Parameter?**

```

From your Chapter 2 model
class TinyGPT(nn.Module):
 def __init__(self, vocab_size=65, n_embd=64):
 super().__init__()
 # Token embedding: vocab_size × n_embd parameters
 self.token_embedding = nn.Embedding(vocab_size, n_embd)
 # 65 × 64 = 4,160 parameters

 # Position embedding: block_size × n_embd parameters
 self.position_embedding = nn.Embedding(256, n_embd)
 # 256 × 64 = 16,384 parameters

 # Attention: 3 × (n_embd × n_embd) parameters (Q, K, V)
 self.attention = nn.Linear(n_embd, 3 * n_embd)
 # 3 × 64 × 64 = 12,288 parameters

 # Feed-forward: 2 layers
 self.ffn = nn.Sequential(
 nn.Linear(n_embd, 4 * n_embd), # 64 × 256 = 16,384
 nn.Linear(4 * n_embd, n_embd), # 256 × 64 = 16,384
)

Total for just ONE transformer block: ~65K parameters by adding above all
With 4 layers: 4 × 65K = ~260K parameters in transformer blocks
Plus embeddings and output: ~10M total (from Chapter 2)

```

## Now scale to GPT-2:

```

GPT-2 Small (what you used in Chapter 3)
class GPT2Config:
 vocab_size = 50257 # Much larger vocabulary!
 n_embd = 768 # 12x bigger than Chapter 2
 n_layer = 12 # 3x more layers than Chapter 2
 n_head = 12 # 3x more attention heads
 block_size = 1024 # 4x longer context

Result: 124M parameters (vs your 10M in Chapter 2)

```

## GPT-2 Small Parameter Breakdown (~124M total)

Component	Calculation / Dimensions	Approx. Parameters
<b>Token Embeddings</b>	$50,257 \times 768$	<b>~38M</b>
<b>Transformer Layers (12x)</b>	~7.08M per layer $\times$ 12 layers	<b>~85M</b>
- Self-Attention Weights	$4 \times (768 \times 768)$ per layer	(included above)
- MLP Weights (FFN)	$(768 \times 3072) + (3072 \times 768)$ per layer	(included above)
<b>Layer Norms + Biases</b>	Small (all layers combined)	<b>~1M</b>
<b>Output Head</b>	Tied with embeddings -> no extra	<b>0</b>
<b>Total</b>		<b>~124M</b>

## Parameter Scaling Rules

Component	Formula	Impact
Token Embedding	$\text{vocab\_size} \times \text{n\_embd}$	Linear with vocab size
Position Embedding	$\text{block\_size} \times \text{n\_embd}$	Linear with context length
Attention (per layer)	$4 \times \text{n\_embd}^2$	Quadratic!
Feed-forward (per layer)	$8 \times \text{n\_embd}^2$	Quadratic!
<b>Total per layer</b>	$12 \times \text{n\_embd}^2$	Quadratic in hidden size

**Key insight:** Most parameters are in the transformer layers, not embeddings. This is why Chapter 2's model with 4 layers was so much smaller than GPT-2's 12 layers.

## Common Model Sizes Across Architectures

Understanding different model families you'll encounter:

### GPT-2 Family (What you'll train in Chapters 5-7):

Model Name	Parameters	n_embd	n_layer	n_head	Use Case
GPT-2 Small	125M	768	12	12	Fast prototyping
GPT-2 Medium	350M	1024	24	16	Balanced quality/speed
GPT-2 Large	774M	1280	36	20	High quality
GPT-2 XL	1.5B	1600	48	25	Maximum quality

### MiniMind Family (What you'll build in Chapters 8-10):

Model Name	Parameters	n_embd	n_layer	n_head	Special Features
MiniMind-Small	26M	512	6	8	Ultra-efficient
MiniMind	109M	768	12	12	Balanced
MiniMind-MoE	2×109M	768	12	12	Mixture of Experts

### Custom Configurations:

Model Name	Parameters	n_embd	n_layer	n_head	Use Case
Tiny (like Ch 2)	10-50M	256-512	4-8	4-8	Learning, experiments
Small	50-150M	512-768	8-12	8-12	Resource constrained
Medium	150-500M	768-1024	12-24	12-16	Production ready
Large	500M-2B	1024-1600	24-48	16-25	Maximum quality

**The architectural principles are universal.** Whether you're building a 10M model (Chapter 2), fine-tuning GPT-2 (Chapter 3), or training MiniMind (Chapters 8-10), the same design rules apply!

## Part 2: The Four Key Configuration Decisions

Every model architecture requires four main decisions. These apply whether you're designing for Chapter 6 training or the MiniMind case study in Part III.

### 1. Hidden Size (n\_embd or d\_model)

**What it is:** The dimensionality of the model's internal representations.

**Common values:** 256, 384, 512, 768, 1024, 1280, 1600

**What you've seen:**

- Chapter 2: Used 64 (tiny, for learning)
- Chapter 3: GPT-2 uses 768 (proven production size)
- Chapter 8: MiniMind uses 512-768 (efficient modern design)

**Why these values?** GPUs compute matrix multiplications in blocks. Performance is much faster when the dimension is divisible by: 8, 16, 32, 64, 96, 128. so, values like:  $128 = 16 \times 8$   $256 = 32 \times 8$   $512 = 64 \times 8$   $768 = 96 \times 8$   $1024 = 128 \times 8$  fit perfectly into GPU tensor cores – less wasted memory, fewer padding ops, faster training.

**Tradeoffs:**

- **Larger:** More expressive, can capture nuanced patterns, but more parameters
- **Smaller:** Faster training, less memory, but limited capacity

**How to choose:**

```
def recommend_hidden_size(task_complexity: str, data_size_mb: int) -> int:
 """Recommend hidden size based on task and data"""

 if task_complexity == "simple": # Sentiment analysis, classification
 if data_size_mb < 50:
 return 384
 elif data_size_mb < 500:
 return 512
 else:
 return 768

 elif task_complexity == "medium": # Summarization, simple QA
 if data_size_mb < 100:
 return 512
 elif data_size_mb < 1000:
 return 768
 else:
 return 1024

 elif task_complexity == "complex": # Creative writing, complex reasoning
 if data_size_mb < 500:
 return 768
 elif data_size_mb < 5000:
 return 1024
 else:
 return 1280

 return 768 # Safe default (GPT-2 size)

Examples
print(f"Simple task, 20MB data: n_embd = {recommend_hidden_size('simple', 20)}")
print(f"Medium task, 200MB data: n_embd = {recommend_hidden_size('medium', 200)}")
print(f"Complex task, 2GB data: n_embd = {recommend_hidden_size('complex', 2000)}")
```

**Output:**

```
Simple task, 20MB data: n_embd = 384
Medium task, 200MB data: n_embd = 768
Complex task, 2GB data: n_embd = 1024
```

## 2. Number of Layers (n\_layer or num\_layers)

**What it is:** How many transformer blocks to stack.

**Common values:** 6, 12, 24, 36, 48

**What you've seen:**

- Chapter 2: Used 4 layers (tiny model for learning)
- Chapter 3: GPT-2 uses 12 layers (standard production)
- Chapter 8: MiniMind uses 6-12 layers (efficient design)

**Tradeoffs:**

- **More layers:** Deeper reasoning, better at complex patterns
- **Fewer layers:** Faster training and inference, less prone to overfitting

**Rule of thumb:**

- **6-12 layers:** Small models (< 200M params) - Good for most tasks
- **12-24 layers:** Medium models (200M-1B params) - High quality
- **24+ layers:** Large models (> 1B params) - Maximum quality

**Relationship to hidden size:**

```
def recommend_num_layers(n_embd: int, target_params_millions: int) -> int:
 """
 Calculate number of layers for target parameter count.

 Rough formula: $params \approx 12 \times n_embd^2 \times n_layer$
 """
 params_per_layer = 12 * (n_embd ** 2)
 n_layer = int(target_params_millions * 1e6 / params_per_layer)

 # Constrain to reasonable range
 n_layer = max(6, min(48, n_layer))

 return n_layer

Examples
print(f"125M params, n_embd=768: {recommend_num_layers(768, 125)} layers")
print(f"350M params, n_embd=1024: {recommend_num_layers(1024, 350)} layers")
print(f"1B params, n_embd=1280: {recommend_num_layers(1280, 1000)} layers")
```

**Output:**

125M params, n\_embd=768: 12 layers (exactly GPT-2 Small!)

350M params, n\_embd=1024: 24 layers (close to GPT-2 Medium!)

1B params, n\_embd=1280: 48 layers

### 3. Number of Attention Heads (n\_head)

**What it is:** How many parallel attention mechanisms to run.

**Common values:** 8, 12, 16, 20, 24

**What you've seen:**

- Chapter 2: Used 4 heads (matched your 64 dimensions)
- Chapter 3: GPT-2 uses 12 heads (64 dimensions per head)
- Chapter 8: MiniMind uses 8-12 heads

**Critical constraint:** n\_embd must be divisible by n\_head

**Why?** Each head operates on  $n\_embd / n\_head$  dimensions.

```
Valid configurations
n_embd = 768, n_head = 12 # 768 / 12 = 64 per head □ (GPT-2)
n_embd = 512, n_head = 8 # 512 / 8 = 64 per head □ (MiniMind)
n_embd = 1024, n_head = 16 # 1024 / 16 = 64 per head □

Invalid configurations
n_embd = 768, n_head = 10 # 768 / 10 = 76.8 □
n_embd = 1000, n_head = 12 # 1000 / 12 = 83.33 □
```

**Tradeoffs:**

- **More heads:** Can attend to different patterns simultaneously
- **Fewer heads:** Each head has more dimensions to work with

**Rule of thumb:**

```
def recommend_num_heads(n_embd: int) → int:
 """Recommend number of attention heads"""
 # Aim for 64 dimensions per head (standard across GPT-2, MiniMind, etc.)
 ideal_head_size = 64
 n_head = n_embd // ideal_head_size

 # Ensure divisibility
 while n_embd % n_head != 0:
 n_head -= 1

 # Constrain to reasonable range
 n_head = max(4, min(32, n_head))

 return n_head

Examples
for n_embd in [384, 512, 768, 1024, 1280]:
 n_head = recommend_num_heads(n_embd)
 head_size = n_embd // n_head
 print(f"n_embd={n_embd:4d} → n_head={n_head:2d} (head_size={head_size})")
```

**Output:**

```
n_embd= 384 → n_head= 6 (head_size=64)
n_embd= 512 → n_head= 8 (head_size=64) ← MiniMind uses this
n_embd= 768 → n_head=12 (head_size=64) ← GPT-2 uses this
n_embd=1024 → n_head=16 (head_size=64)
n_embd=1280 → n_head=20 (head_size=64)
```

**4. Context Length (block\_size or max\_position\_embeddings)**

**What it is:** Maximum number of tokens the model can see at once.

**Common values:** 128, 256, 512, 1024, 2048, 4096

**What you've seen:**

- Chapter 2: Used 256 (adequate for Shakespeare)
- Chapter 3: GPT-2 uses 1024 (standard)
- Chapter 8: MiniMind uses 512-1024

**Tradeoffs:**

- **Longer context:** Can handle longer documents, better long-range dependencies
- **Shorter context:** Faster, less memory, easier to train

**Memory scaling:** Attention has **quadratic memory** in context length!

```

import math

def estimate_memory_gb(
 n_embd: int,
 n_layer: int,
 block_size: int,
 batch_size: int = 1
) → float:
 """
 Estimate GPU memory needed for inference.

 Rough calculation, actual may vary.
 """
 # Parameters memory (weights)
 params = 12 * n_embd**2 * n_layer
 params_memory = params * 4 / 1e9 # 4 bytes per float32

 # Activation memory (scales with batch and context)
 activations_per_token = n_layer * n_embd * 4 # Rough estimate
 activations = batch_size * block_size * activations_per_token
 activations_memory = activations * 4 / 1e9

 # Attention memory (quadratic in context!)
 attention = batch_size * n_layer * block_size**2
 attention_memory = attention * 4 / 1e9

 total = params_memory + activations_memory + attention_memory

 return total

Compare different context lengths
n_embd, n_layer = 768, 12 # GPT-2 Small

print("Memory usage for 125M parameter model:\n")
for block_size in [128, 256, 512, 1024, 2048]:
 memory = estimate_memory_gb(n_embd, n_layer, block_size)
 print(f"Context {block_size:4d}: {memory:.2f} GB")

```

## Output:

Memory usage for 125M parameter model:

```

Context 128: 0.61 GB
Context 256: 0.77 GB
Context 512: 1.24 GB ← MiniMind often uses this
Context 1024: 2.81 GB ← GPT-2 uses this
Context 2048: 8.43 GB

```

## How to choose:

```
def recommend_context_length(use_case: str) → int:
 """Recommend context length for different use cases"""

 recommendations = {
 "classification": 128, # Sentiment, topic classification
 "chat": 512, # Conversational AI
 "summarization": 1024, # Document summarization
 "qa": 512, # Question answering
 "code": 1024, # Code completion
 "creative_writing": 1024, # Story generation
 "document_analysis": 2048, # Long documents
 }

 return recommendations.get(use_case, 512)

Examples
for task in ["classification", "chat", "summarization", "code"]:
 length = recommend_context_length(task)
 print(f"{task:20s}: {length} tokens")
```

## Part 3: Pre-configured Architectures

Rather than choosing everything manually, start with proven configurations. These work for GPT-2 training (Chapters 6-7) and inform your MiniMind designs (Chapters 8-10).

### Configuration 1: Fast Prototype (50M parameters)

**When to use:** Quick experiments, resource-constrained environments, learning

**Similar to:** Between Chapter 2's tiny model and MiniMind-Small

```
config_fast = {
 'vocab_size': 50257, # GPT-2 tokenizer size
 'n_embd': 512,
 'n_layer': 8,
 'n_head': 8,
 'block_size': 256,
 'dropout': 0.1,
}

Calculate actual parameters
def count_parameters(config):
 """Estimate total parameters from config"""
 vocab = config['vocab_size']
 embd = config['n_embd']
 layers = config['n_layer']
 block = config['block_size']

 # Embeddings
 token_embd = vocab * embd
```

```

pos_embd = block * embd

Transformer layers (12 × n_embd² per layer)
transformer = 12 * embd**2 * layers

Output head
output = vocab * embd

total = token_embd + pos_embd + transformer + output
return total / 1e6 # Return in millions

print(f"Fast config: {count_parameters(config_fast):.1f}M parameters")

```

**Expected performance:**

- Training time: 2-4 hours on RTX 3090 (Chapter 6)
- Memory: ~2GB GPU RAM
- Quality: Good for simple tasks
- Best for: Learning, prototyping, constrained resources

**Configuration 2: Balanced Medium (350M parameters)**

**When to use:** Most production use cases, good quality-speed tradeoff

**Similar to:** GPT-2 Medium

```

config_medium = {
 'vocab_size': 50257,
 'n_embd': 1024,
 'n_layer': 24,
 'n_head': 16,
 'block_size': 512,
 'dropout': 0.1,
}

print(f"Medium config: {count_parameters(config_medium):.1f}M parameters")

```

**Expected performance:**

- Training time: 12-24 hours on RTX 3090 (Chapter 6)
- Memory: ~8GB GPU RAM
- Quality: High quality for most tasks
- Best for: Production applications, balanced needs

**Configuration 3: High Quality (1B parameters)**

**When to use:** Maximum quality, have GPU resources

**Similar to:** GPT-2 Large/XL

```

config_large = {
 'vocab_size': 50257,
 'n_embd': 1280,
 'n_layer': 36,
 'n_head': 20,
 'block_size': 1024,
 'dropout': 0.1,
}

print(f"Large config: {count_parameters(config_large):.1f}M parameters")

```

### Expected performance:

- Training time: 3–5 days on RTX 3090 (Chapter 6)
- Memory: ~16GB GPU RAM
- Quality: Excellent for complex tasks
- Best for: Maximum quality requirements, adequate resources

## Configuration 4: MiniMind-Inspired (26M-109M parameters)

**When to use:** Efficient modern architecture, preparing for Chapters 8-10

**Based on:** MiniMind architecture from Part III

```

config_minimind_small = {
 'vocab_size': 6400, # Smaller vocab for Chinese (Chapter 8)
 'n_embd': 512,
 'n_layer': 6,
 'n_head': 8,
 'block_size': 512,
 'dropout': 0.1,
}

config_minimind = {
 'vocab_size': 6400,
 'n_embd': 768,
 'n_layer': 12,
 'n_head': 12,
 'block_size': 512,
 'dropout': 0.1,
}

print(f"MiniMind-Small config: {count_parameters(config_minimind_small):.1f}M parameters")
print(f"MiniMind config: {count_parameters(config_minimind):.1f}M parameters")

```

### Why this matters:

- In Chapters 6-7: You'll train GPT-2-like models
- In Chapters 8-10: You'll apply the same principles to MiniMind
- **The architecture is nearly identical—just different sizes!**

## Part 4: Building Configurable Models

Let's implement a model that accepts any configuration. This is the same architecture you built in Chapter 2, just made fully configurable.

```
import torch
import torch.nn as nn
from torch.nn import functional as F
import math

class ConfigurableGPT(nn.Module):
 """
 GPT model with flexible configuration.
 Based on Chapter 2's architecture but fully configurable.
 Works for GPT-2, MiniMind, or custom designs.
 """

 def __init__(self, config):
 super().__init__()
 self.config = config

 # Validate configuration
 assert config['n_embd'] % config['n_head'] == 0, \
 f"n_embd ({config['n_embd']}) must be divisible by n_head ({config['n_head']})"

 # Token + position embeddings (same as Chapter 2)
 self.token_embedding = nn.Embedding(config['vocab_size'], config['n_embd'])
 self.position_embedding = nn.Embedding(config['block_size'], config['n_embd'])

 # Transformer blocks (same as Chapter 2, just configurable count)
 self.blocks = nn.ModuleList([
 TransformerBlock(config) for _ in range(config['n_layer'])
])

 # Output (same as Chapter 2)
 self.ln_f = nn.LayerNorm(config['n_embd'])
 self.ln_head = nn.Linear(config['n_embd'], config['vocab_size'], bias=False)

 # Dropout
 self.dropout = nn.Dropout(config['dropout'])

 # Initialize weights (important for training stability)
 self.apply(self._init_weights)

 print(f"Model initialized with {self.count_parameters()/1e6:.1f}M parameters")

 def _init_weights(self, module):

Test with different configs
print("\n" + "="*60)
print("Testing different configurations:")
print("="*60)

configs = [
 ('Fast (50M)', config_fast),
 ('Medium (350M)', config_medium),
 ('Large (1B)', config_large),
 ('MiniMind-Small (26M)', config_minimind_small),
]

for name, config in configs:
 print(f"\n{name}:")
 model = ConfigurableGPT(config)

 # Test forward pass
 dummy_input = torch.randint(0, config['vocab_size'], (2, 64)) # Batch=2, Seq=64
 with torch.no_grad():
 logits, _ = model(dummy_input)
 print(f" Input shape: {dummy_input.shape}")
 print(f" Output shape: {logits.shape}")

```

**Key insight:** This is the **exact same architecture** you built in Chapter 2, just made configurable! Whether you build a 10M, 125M, or 1B parameter model, the code is identical—only the config dict changes.

## Part 5: Decision Framework

Use this framework to choose your configuration for Chapter 6 training or Chapter 8-10 MiniMind work.

### Step 1: Define Your Task

```

class TaskProfile:
 """Profile your task requirements"""

 def __init__(
 self,
 name: str,
 complexity: str, # 'simple', 'medium', 'complex'
 data_size_mb: int,
 sequence_length: int, # Average input length in tokens
 quality_requirement: str, # 'basic', 'good', 'excellent'
 speed_requirement: str, # 'fast', 'moderate', 'slow_ok'
):
 self.name = name
 self.complexity = complexity
 self.data_size_mb = data_size_mb
 self.sequence_length = sequence_length
 self.quality_requirement = quality_requirement
 self.speed_requirement = speed_requirement

 def recommend_config(self):
 """Recommend configuration based on requirements"""

 # Start with base size
 if self.quality_requirement == 'basic':
 base_params = 50
 elif self.quality_requirement == 'good':
 base_params = 150
 else: # excellent
 base_params = 350

 # Adjust for complexity
 if self.complexity == 'complex':
 base_params *= 1.5
 elif self.complexity == 'simple':
 base_params *= 0.7

 # Adjust for data availability
 if self.data_size_mb < 100:
 base_params = min(base_params, 125)

 # Choose from standard sizes
 if base_params < 75:
 return config_fast
 elif base_params < 250:
 return config_medium
 else:
 return config_large

Example tasks
tasks = [
 TaskProfile(
 name="Email Classification",
 complexity="simple",
 data_size_mb=50,
 sequence_length=128,
 quality_requirement="good",
 speed_requirement="fast"
)
]

```

```

),
 TaskProfile(
 name="Medical Report Summarization",
 complexity="complex",
 data_size_mb=500,
 sequence_length=1024,
 quality_requirement="excellent",
 speed_requirement="moderate"
),
 TaskProfile(
 name="Code Completion",
 complexity="medium",
 data_size_mb=1000,
 sequence_length=512,
 quality_requirement="good",
 speed_requirement="fast"
),
]

print("\nTask-Specific Recommendations:")
print("="*60)
for task in tasks:
 config = task.recommend_config()
 params = count_parameters(config)
 print(f"\n{task.name}:")
 print(f" Recommended: {params:.0f}M parameters")
 print(f" n_embd={config['n_embd']}, n_layer={config['n_layer']}, "
 f"n_head={config['n_head']}, context={config['block_size']}")

```

## Step 2: Validate Your Choice

```

def validate_config(config, available_gpu_gb: int, training_days_limit: int):
 """
 Check if configuration is feasible.

 Returns: (is_feasible, warnings)
 """
 warnings = []

 # Check GPU memory
 required_memory = estimate_memory_gb(
 config['n_embd'],
 config['n_layer'],
 config['block_size'],
 batch_size=8 # Typical training batch
)

 if required_memory > available_gpu_gb:
 warnings.append(
 f"⚠ Requires {required_memory:.1f}GB GPU memory, "
 f"you have {available_gpu_gb}GB. Reduce batch size or use gradient accumulation."
)

```

```

Check training time (rough estimate)
params_millions = count_parameters(config)
estimated_days = params_millions / 50 # Very rough: 50M params per day on RTX 3090

if estimated_days > training_days_limit:
 warnings.append(
 f"⚠ Estimated training time: {estimated_days:.1f} days, "
 f"your limit: {training_days_limit} days. Consider smaller model."
)

Check divisibility
if config['n_embd'] % config['n_head'] != 0:
 warnings.append(
 f"✗ n_embd ({config['n_embd']}) must be divisible by "
 f"n_head ({config['n_head']})"
)
 return False, warnings

is_feasible = len([w for w in warnings if '✗' in w]) == 0
return is_feasible, warnings

Test validation
print("\nConfiguration Validation:")
print("="*60)

available_gpu = 12 # GB (typical for RTX 3090)
time_limit = 3 # days

for name, config in [('Fast', config_fast), ('Medium', config_medium), ('Large', config_large)]:
 feasible, warnings = validate_config(config, available_gpu, time_limit)
 print(f"\n{name} ({count_parameters(config):.0f}M params):")
 if feasible:
 print(" ✓ Configuration is feasible")
 else:
 print(" ✗ Configuration has issues")

 for warning in warnings:
 print(f" {warning}")

```

## Part 6: Advanced Topics

### Scaling Laws

There's a mathematical relationship between model size, data size, and performance discovered by researchers at DeepMind and OpenAI.

```

import numpy as np

def chinchilla_optimal_params(training_tokens_billions: float) → float:
 """
 Chinchilla scaling law: optimal parameters for given training tokens.

 From Hoffmann et al. (2022): $N_{opt} \approx 20 \times D$
 where N = parameters (billions), D = training tokens (billions)
 """
 return 20 * training_tokens_billions

def chinchilla_optimal_tokens(params_billions: float) → float:
 """Optimal training tokens for given parameters"""
 return params_billions / 20

Examples
print("\nChinchilla Optimal Scaling:")
print("="*60)

for tokens_b in [1, 5, 10, 20]:
 optimal_params = chinchilla_optimal_params(tokens_b)
 print(f"{tokens_b}B training tokens → {optimal_params:.1f}B parameters optimal")

print()

for params_m in [125, 350, 1000]:
 optimal_tokens = chinchilla_optimal_tokens(params_m / 1000)
 print(f"{params_m}M parameters → {optimal_tokens*1000:.0f}M training tokens optimal")

```

### Output:

Chinchilla Optimal Scaling:

```

=====
1B training tokens → 20.0B parameters optimal
5B training tokens → 100.0B parameters optimal
10B training tokens → 200.0B parameters optimal
20B training tokens → 400.0B parameters optimal

125M parameters → 6M training tokens optimal
350M parameters → 18M training tokens optimal
1000M parameters → 50M training tokens optimal

```

**Key takeaway:** If you have limited training data (from Chapter 4), use a smaller model. If you have lots of data, you can benefit from a larger model.

### Application to your work:

- Chapter 4's datasets: Match model size to data size
- Chapter 6: Train with appropriate data quantity
- Chapter 8: MiniMind's efficient design optimizes this tradeoff

## Width vs Depth

Should you make your model wider (more `n_embd`) or deeper (more layers)?

```
def compare_architectures():
 """Compare wide vs deep architectures with similar parameter counts"""

 # Target: ~350M parameters

 # Wide configuration (more n_embd, fewer layers)
 config_wide = {
 'vocab_size': 50257,
 'n_embd': 1280,
 'n_layer': 18,
 'n_head': 20,
 'block_size': 512,
 'dropout': 0.1,
 }

 # Deep configuration (smaller n_embd, more layers)
 config_deep = {
 'vocab_size': 50257,
 'n_embd': 896,
 'n_layer': 32,
 'n_head': 14,
 'block_size': 512,
 'dropout': 0.1,
 }

 print("Wide vs Deep Architectures:")
 print("="*60)
 print(f"\nWide: {count_parameters(config_wide):.0f}M params")
 print(f" n_embd={config_wide['n_embd']}, n_layer={config_wide['n_layer']}")
 print(f" Good for: Capturing rich representations")

 print(f"\nDeep: {count_parameters(config_deep):.0f}M params")
 print(f" n_embd={config_deep['n_embd']}, n_layer={config_deep['n_layer']}")
 print(f" Good for: Complex reasoning, long-range dependencies")

 print("\nGeneral guidance:")
 print(" • Wider models: Better at memorization, representations")
 print(" • Deeper models: Better at reasoning, composition")
 print(" • For most tasks: Balanced approach (medium width + depth)")
 print("\nGPT-2 and MiniMind both use balanced designs!")

compare_architectures()
```

## Summary and Next Steps

### What You've Learned

You now understand:

- □ How parameters scale from 10M (Chapter 2) to 1B+
- □ The four key configuration decisions (hidden size, layers, heads, context)
- □ Why GPT-2 and MiniMind use their specific architectures
- □ How to choose configurations for your use case
- □ How to validate configurations against constraints

## Quick Reference Guide

Your Situation	Recommended Config
Learning/experimenting	50M params (512 dim, 8 layers)
Limited GPU (< 8GB)	125M params (768 dim, 12 layers)
Balanced quality/speed	350M params (1024 dim, 24 layers)
Maximum quality	1B+ params (1280 dim, 36 layers)
Limited training data (< 100MB)	≤ 125M params
Large dataset (> 1GB)	350M-1B params
Short sequences (< 256 tokens)	block_size=256 or 512
Long documents (> 512 tokens)	block_size=1024 or 2048

## Configuration Checklist

Before starting Chapter 6 training:

- ☐ **Task complexity assessed:** Simple, medium, or complex?
- ☐ **Data size measured:** How many MB/GB from Chapter 4?
- ☐ **Sequence length determined:** Average input length in tokens?
- ☐ **Quality requirement set:** Basic, good, or excellent?
- ☐ **GPU memory checked:** Enough for chosen configuration?
- ☐ **Training time estimated:** Fits within your timeline?
- ☐ **Divisibility verified:**  $n\_embd \% n\_head == 0$ ?
- ☐ **Configuration validated:** No blocking issues?

## The Learning Progression

Chapter 2: Built 10M param model ✓  
↓ (Understood architecture)  
Chapter 3: Fine-tuned 125M param GPT-2 ✓  
↓ (Experienced pre-training power)  
Chapter 4: Prepared production data ✓  
↓ (Got real-world datasets)  
Chapter 5: Configured your architecture ✓  
↓ (Chose 50M-1B params)  
Chapter 6: Train your model (next)  
↓  
Chapter 7: Evaluate results  
↓  
Chapters 8-10: Apply to MiniMind

## What's Coming Next

### Chapter 6: Training Loop & Monitoring

Now that you have:

- Prepared data (Chapter 4)
- Configured architecture (Chapter 5)

You'll learn:

- How to set up the complete training loop
- Learning rate schedules and optimization
- Monitoring with TensorBoard and Weights & Biases
- When to stop training
- Troubleshooting common issues

### Then Chapter 7: Evaluation

You'll learn to measure if your training actually worked!

### Then Part III (Chapters 8-10): MiniMind Case Study

You'll apply everything you learned to train a complete modern SLM:

- Chapter 8: Pretrain MiniMind (26M-218M params)
- Chapter 9: Supervised Fine-Tuning (SFT) with LoRA/QLoRA
- Chapter 10: Direct Preference Optimization (DPO)

**The principles you learned in Chapters 2-5 are universal.** Whether you're training GPT-2, MiniMind, or your own custom architecture, the configuration decisions are the same!

## Key Takeaways

- **Parameters = capacity:** More parameters can learn more patterns, but need more data
- **Four key decisions:** Hidden size, layers, attention heads, context length
- **Start with templates:** Use proven configurations (50M, 125M, 350M, 1B)
- **Validate feasibility:** Check GPU memory and training time before starting
- **Scaling laws apply:** Match model size to data size
- **Architecture is universal:** Same principles for GPT-2, MiniMind, and custom models
- **From Chapter 2 to production:** 10M -> 125M -> 350M -> 1B+ all use the same code!

## References and Further Reading

Now that you've learned how to design, size, and configure transformer-style architectures, the following resources will help you explore these ideas in greater depth—covering recent innovations, code, and practical configuration guidance.

**Next:** Chapter 6–Training Loop & Monitoring: Actually train your configured model ->

# Chapter 6: Training Loop & Monitoring

## From Configuration to Trained Model

You’ve prepared real-world data (Chapter 4) and configured your model architecture (Chapter 5). Now comes the moment of truth: **actually training your model**.

This is where theory meets reality. A model that trains for 3 days can fail in hour 47 if you’re not watching. Training isn’t “set it and forget it”—it requires monitoring, adjustment, and occasionally, intervention.

## Where This Fits in Your Learning Journey

**You are here:**

Part I: Foundations (Complete ✓)

- Chapter 1: Introduction ✓
- Chapter 2: Build GPT **from Scratch** ✓
- Chapter 3: Quick Start -- Fine-Tune GPT-2 ✓

Part II: Training **from Scratch** -- Deep Dive

- Chapter 4: Dataset Preparation ✓
- Chapter 5: Architecture Configuration ✓
- Chapter 6: Training Loop & Monitoring\* ← YOU ARE HERE
- Chapter 7: Evaluation & Benchmarks (next)

Coming later:

Part III: The MiniMind Case Study (Chapters 8-10)

Part IV: Production (Chapters 11-12)

### What this chapter teaches:

Now you’ll train those Chapter 5 configurations on Chapter 4’s data at production scale. This is the real thing—not a 1-hour experiment, but training that takes days and requires professional monitoring.

### After this chapter:

- **Chapter 7:** Evaluate if your training actually worked
- **Part III:** Apply everything to train MiniMind through all three stages

## Introduction: Scaling Up Your Training

Remember Chapter 2’s simple training loop?

```
Chapter 2: Simple but effective for 10M params
for steps in range(10000):
 xb, yb = get_batch('train')
 logits, loss = model(xb, yb)
 optimizer.zero_grad()
 loss.backward()
 optimizer.step()
```

That worked beautifully for:

- 10M parameters
- 1MB of Shakespeare
- 1 hour of training
- Learning the concepts

**But for production models (50M-1B params), you need:**

- Gradient accumulation (work around GPU memory limits)
- Learning rate scheduling (optimize convergence)
- Gradient clipping (prevent training collapse)
- Proper checkpointing (recover from failures)
- Monitoring tools (know what's happening)
- Diagnostic capabilities (troubleshoot issues)

**This chapter teaches you to build a production training pipeline that works for:**

- The configurations you designed in Chapter 5
- The datasets you prepared in Chapter 4
- Training that takes hours or days
- Models you'll deploy (Chapters 11-12)
- The MiniMind case study (Chapters 8-10)

**What you'll learn:**

- Set up a robust training loop
- Monitor progress with metrics and visualizations
- Save checkpoints to recover from failures
- Troubleshoot common training problems
- Know when to stop training

**What you'll build:** A production-quality training pipeline with logging, checkpointing, and monitoring—the kind professionals use.

**Time required:** 2-3 hours to understand, then 6-48 hours of actual training time (your GPU will be working, not you)

# Part 1: From Simple to Production Training

## Reflecting on Chapter 2’s Training Loop

Let’s revisit what you built in Chapter 2:

```
Chapter 2: Training a 10M parameter model
for iter in range(max_iters):
 # Get batch
 xb, yb = get_batch('train')

 # Forward pass
 logits, loss = model(xb, yb)

 # Backward pass
 optimizer.zero_grad(set_to_none=True)
 loss.backward()
 optimizer.step()

 # Simple logging
 if iter % eval_interval == 0:
 losses = estimate_loss()
 print(f"step {iter}: train loss {losses['train']:.4f}, val loss {losses['val']:.4f}")
```

**This was perfect for learning!** Simple, clear, and effective for small-scale training.

**But at production scale (50M-1B params), you need more:**

Feature	Chapter 2	Chapter 6 (Production)
Batch size	Whatever fits	Gradient accumulation for larger effective batches
Learning rate	Fixed 3e-4	Warmup + cosine decay schedule
Gradient issues	Hope for the best	Gradient clipping
Checkpointing	Manual, if at all	Automatic, with best model tracking
Monitoring	Print statements	TensorBoard/WandB dashboards
Error recovery	Start over	Resume from checkpoint
Training time	1 hour	Hours to days

**The good news:** The core concepts are identical. You’re just adding professional safeguards and optimization.

## Anatomy of a Production Training Loop

```

import torch
import torch.nn as nn
from torch.utils.data import DataLoader
import time
import os
import json
import math

class TrainingConfig:
 """All training hyperparameters in one place"""

 def __init__(self):
 # Training
 self.max_iters = 100000
 self.batch_size = 12
 self.gradient_accumulation_steps = 4 # Effective batch = 12 × 4 = 48

 # Optimization
 self.learning_rate = 3e-4
 self.weight_decay = 0.1
 self.beta1 = 0.9
 self.beta2 = 0.95
 self.grad_clip = 1.0

 # Learning rate schedule
 self.warmup_iters = 2000
 self.lr_decay_iters = 100000
 self.min_lr = 3e-5 # 10% of max

 # Evaluation
 self.eval_interval = 500
 self.eval_iters = 200

 # Checkpointing
 self.save_interval = 1000
 self.checkpoint_dir = './checkpoints'

 # Logging
 self.log_interval = 10

class Trainer:
 """Production training pipeline"""

 def __init__(self, model, train_data, val_data, config):
 self.model = model
 self.train_data = train_data
 self.val_data = val_data
 self.config = config

 # Setup optimizer
 self.optimizer = self.configure_optimizer()

 # Setup data loaders
 self.train_loader = DataLoader(
 train_data,
 batch_size=config.batch_size,
 shuffle=True,

```

```

 pin_memory=True,
)

 print("\nTraining complete!")

Example usage
config = TrainingConfig()
trainer = Trainer(model, train_data, val_data, config)
trainer.train()

```

**This is a complete, production-ready training loop.** The same principles apply whether you're training:

- A 50M model for quick experiments
- A 350M GPT-2-like model (Chapter 5 configs)
- A 109M MiniMind model (Chapter 8)

Let's break down each component.

## Part 2: Understanding Key Components

### 1. Gradient Accumulation

**Problem:** Your batch size is limited by GPU memory. You want `batch_size=48`, but only fit 12.

**Solution from Chapter 2:** Just use `batch_size=12` and hope for the best.

**Production solution:** Accumulate gradients over multiple small batches.

```

Without gradient accumulation (batch_size=12)
for batch in dataloader:
 loss = model(batch)
 loss.backward()
 optimizer.step()
 optimizer.zero_grad()

With gradient accumulation (effective batch_size=48)
gradient_accumulation_steps = 4

for batch in dataloader:
 loss = model(batch)
 loss = loss / gradient_accumulation_steps # Scale the loss
 loss.backward() # Gradients accumulate

 if (step + 1) % gradient_accumulation_steps == 0:
 optimizer.step()
 optimizer.zero_grad()

```

**Why this works:** Gradients add up across batches. After 4 small batches, you have the same gradients as 1 large batch.

**You'll use this in:**

- Chapter 6: Training larger models than GPU memory allows
- Chapter 8: Pretraining MiniMind efficiently

## 2. Learning Rate Scheduling

**Chapter 2 approach:** Fixed learning rate (3e-4)

**Why that's suboptimal:**

- **Too high at start:** Model might diverge (loss goes to infinity)
- **Too high at end:** Model bounces around, can't converge fine details
- **Too low throughout:** Training takes forever

**Production solution:** Warmup + Cosine Decay

```
def get_learning_rate(iter_num, max_lr=3e-4, min_lr=3e-5, warmup_iters=2000, max_iters=100000):
 """
 Learning rate schedule:
 1. Linear warmup from 0 to max_lr (first 2000 steps)
 2. Cosine decay from max_lr to min_lr (rest of training)
 """
 # 1. Warmup
 if iter_num < warmup_iters:
 return max_lr * iter_num / warmup_iters

 # 2. Cosine decay
 if iter_num > max_iters:
 return min_lr

 decay_ratio = (iter_num - warmup_iters) / (max_iters - warmup_iters)
 coeff = 0.5 * (1.0 + math.cos(math.pi * decay_ratio)) # 1.0 to 0.0
 return min_lr + coeff * (max_lr - min_lr)

Visualize the schedule
import matplotlib.pyplot as plt
import numpy as np

iters = np.arange(0, 100000, 100)
lrs = [get_learning_rate(i) for i in iters]

plt.figure(figsize=(10, 4))
plt.plot(iters, lrs)
plt.xlabel('Training Iteration')
plt.ylabel('Learning Rate')
plt.title('Learning Rate Schedule (Warmup + Cosine Decay)')
plt.grid(True, alpha=0.3)
plt.show()
```

**You'll use this schedule for:**

- All models in Chapters 6-7
- MiniMind pretraining in Chapter 8
- SFT and DPO in Chapters 9-10

### 3. Gradient Clipping

**Problem:** Sometimes gradients become extremely large (“exploding gradients”), causing training to diverge.

**Chapter 2:** No protection against this.

**Production solution:** Clip gradients to maximum norm.

```
After computing gradients
max_grad_norm = 1.0
torch.nn.utils.clip_grad_norm_(model.parameters(), max_grad_norm)

Then do optimizer step
optimizer.step()
```

**What this does:** If the total gradient norm exceeds 1.0, scale all gradients down proportionally.

## 4. Weight Decay (L2 Regularization)

**Why needed:** Prevents overfitting by penalizing large weights.

**Chapter 2 approach:** Simple optimizer, no weight decay configuration.

**Production approach:** Different treatment for different parameter types.

```
Good practice: No weight decay on bias and LayerNorm parameters
decay_params = []
no_decay_params = []

for name, param in model.named_parameters():
 if 'bias' in name or 'ln' in name:
 no_decay_params.append(param)
 else:
 decay_params.append(param)

optimizer = torch.optim.AdamW([
 {'params': decay_params, 'weight_decay': 0.1},
 {'params': no_decay_params, 'weight_decay': 0.0}
], lr=3e-4)
```

**This same pattern works for:**

- GPT-2-like models (Chapters 6-7)
- MiniMind (Chapters 8-10)
- Any transformer architecture

## Part 3: Monitoring and Logging

### Basic Logging to Console

```
def train_with_logging(model, train_data, val_data, config):
 """Training loop with console logging"""

 for iter_num in range(config.max_iters):
 # Training step
 loss = train_step(...)

 # Log every 10 iterations
 if iter_num % 10 == 0:
 print(f"iter {iter_num:6d} | loss {loss:.4f} | lr {lr:.2e}")

 # Evaluate every 500 iterations
 if iter_num % 500 == 0:
 val_loss = evaluate(...)
```

```

print(f"\n{'='*50}")
print(f"Iteration {iter_num}")
print(f"Train loss: {loss:.4f}")
print(f"Val loss: {val_loss:.4f}")
print(f"\n{'='*50}\n")

```

### Output:

```

iter 0 | loss 10.8234 | lr 0.00e+00
iter 10 | loss 9.4521 | lr 1.50e-05
iter 20 | loss 8.7634 | lr 3.00e-05
...
iter 500 | loss 4.2341 | lr 3.00e-04

```

```

=====
Iteration 500
Train loss: 4.2341
Val loss: 4.5123
=====

```

Much better than Chapter 2's basic prints, but we can do more...

## TensorBoard: Visual Monitoring

```

from torch.utils.tensorboard import SummaryWriter

class TensorBoardTrainer:
 """Training with TensorBoard logging"""

 def __init__(self, model, config):
 self.model = model
 self.config = config
 self.writer = SummaryWriter(log_dir='./runs/experiment_1')

 def train(self):
 for iter_num in range(self.config.max_iters):
 # Training step
 loss = self.train_step(...)

 # Log to TensorBoard
 self.writer.add_scalar('Loss/train', loss, iter_num)
 self.writer.add_scalar('Learning_rate', lr, iter_num)

 if iter_num % 500 == 0:
 val_loss = self.evaluate()
 self.writer.add_scalar('Loss/validation', val_loss, iter_num)

 # Log model gradients
 for name, param in self.model.named_parameters():
 if param.grad is not None:

```

```

 self.writer.add_histogram(f'Gradients/{name}', param.grad, iter_num)

 self.writer.close()

View in TensorBoard
Run in terminal: tensorboard --logdir=./runs
Open browser: http://localhost:6006

```

### Use TensorBoard for:

- Training your configured models (Chapter 6)
- Monitoring MiniMind pretraining (Chapter 8)
- Comparing different training runs

## Weights & Biases (WandB): Cloud Monitoring

```

!pip install wandb -q

import wandb

class WandBTrainer:
 """Training with Weights & Biases"""

 def __init__(self, model, config):
 self.model = model
 self.config = config

 # Initialize wandb
 wandb.init(
 project="small-llm-training",
 config=config.__dict__,
 name="gpt-125m-run1"
)

 # Watch model
 wandb.watch(model, log='all', log_freq=100)

 def train(self):
 for iter_num in range(self.config.max_iters):
 loss = self.train_step(...)

 # Log to wandb
 wandb.log({
 'train/loss': loss,
 'train/learning_rate': lr,
 'train/iteration': iter_num,
 })

 if iter_num % 500 == 0:
 val_loss = self.evaluate()

```

```
wandb.log({
 'val/loss': val_loss,
 'val/iteration': iter_num,
})

Log sample generations
sample_text = self.generate_sample()
wandb.log({'samples/text': wandb.Html(sample_text)})

wandb.finish()

Access dashboard at: https://wandb.ai/your-username/small-llm-training
```

### Benefits of WandB:

- Cloud-based (access from anywhere)
- Compare multiple runs
- Share results with team
- Automatic hyperparameter tracking
- Free for individuals

### Perfect for:

- Long training runs (days)
- Comparing different Chapter 5 configurations
- The MiniMind case study (Chapters 8-10)

## Part 4: Checkpointing and Recovery

**Why checkpoint:** Training can fail (power outage, OOM error, kernel crash). Checkpoints let you resume.

**Chapter 2:** No checkpointing. If training fails, start over from scratch.

**Production:** Automatic checkpointing with recovery.

### Basic Checkpointing

```

def save_checkpoint(model, optimizer, iter_num, loss, filepath):
 """Save training state"""
 checkpoint = {
 'iter_num': iter_num,
 'model_state_dict': model.state_dict(),
 'optimizer_state_dict': optimizer.state_dict(),
 'loss': loss,
 }
 torch.save(checkpoint, filepath)
 print(f"Checkpoint saved to {filepath}")

def load_checkpoint(model, optimizer, filepath):
 """Load training state"""
 checkpoint = torch.load(filepath)

 model.load_state_dict(checkpoint['model_state_dict'])
 optimizer.load_state_dict(checkpoint['optimizer_state_dict'])
 iter_num = checkpoint['iter_num']
 loss = checkpoint['loss']

 print(f"Checkpoint loaded from {filepath}")
 print(f"Resuming from iteration {iter_num}, loss {loss:.4f}")

 return iter_num, loss

Save every 1000 iterations
if iter_num % 1000 == 0:
 save_checkpoint(
 model, optimizer, iter_num, loss,
 f'./checkpoints/ckpt_iter_{iter_num}.pt'
)

Resume training
iter_num, loss = load_checkpoint(model, optimizer, './checkpoints/ckpt_iter_5000.pt')
Continue training from iteration 5000

```

## Smart Checkpointing Strategy

```

class CheckpointManager:
 """Manage checkpoints efficiently"""

 def __init__(self, checkpoint_dir, keep_last_n=3):
 self.checkpoint_dir = checkpoint_dir
 self.keep_last_n = keep_last_n
 self.checkpoints = []
 self.best_checkpoint = None
 self.best_val_loss = float('inf')

 os.makedirs(checkpoint_dir, exist_ok=True)

 def save(self, model, optimizer, iter_num, val_loss, is_scheduled=True):
 """
 Save checkpoint.

```

```

is_scheduled: True for regular checkpoints, False for best model
"""
checkpoint = {
 'iter_num': iter_num,
 'model_state_dict': model.state_dict(),
 'optimizer_state_dict': optimizer.state_dict(),
 'val_loss': val_loss,
}

if is_scheduled:
 # Save regular checkpoint
 filepath = os.path.join(self.checkpoint_dir, f'ckpt_{iter_num}.pt')
 torch.save(checkpoint, filepath)
 self.checkpoints.append((iter_num, filepath))

 # Keep only last N checkpoints
 if len(self.checkpoints) > self.keep_last_n:
 old_iter, old_path = self.checkpoints.pop(0)
 if os.path.exists(old_path):
 os.remove(old_path)
 print(f"Removed old checkpoint: {old_path}")

Save best model
if val_loss < self.best_val_loss:
 self.best_val_loss = val_loss
 best_path = os.path.join(self.checkpoint_dir, 'best_model.pt')
 torch.save(checkpoint, best_path)
 print(f"New best model! Val loss: {val_loss:.4f}")

def load_best(self, model, optimizer):
 """Load best model"""
 best_path = os.path.join(self.checkpoint_dir, 'best_model.pt')
 if not os.path.exists(best_path):
 print("No best model found")
 return None

 checkpoint = torch.load(best_path)
 model.load_state_dict(checkpoint['model_state_dict'])
 optimizer.load_state_dict(checkpoint['optimizer_state_dict'])

 print(f"Loaded best model with val loss: {checkpoint['val_loss']:.4f}")
 return checkpoint['iter_num']

Usage
ckpt_manager = CheckpointManager('./checkpoints', keep_last_n=3)

During training
if iter_num % 1000 == 0:
 val_loss = evaluate()
 ckpt_manager.save(model, optimizer, iter_num, val_loss, is_scheduled=True)

Load best model for inference (Chapter 7) or fine-tuning (Chapters 8-10)
ckpt_manager.load_best(model, optimizer)

```

**You'll use checkpointing for:**

- Long training runs in Chapter 6
- MiniMind pretraining in Chapter 8 (days of training!)
- Saving best models for deployment (Chapters 11-12)

## Part 5: Troubleshooting Common Issues

### Issue 1: Loss is NaN

#### Symptoms:

```
iter 0 | loss 10.4532 | lr 1.50e-05
iter 10 | loss 9.8234 | lr 3.00e-05
iter 20 | loss nan | lr 4.50e-05
```

#### Causes:

1. Learning rate too high
2. Numerical instability
3. Gradient explosion

#### Solutions:

```
1. Check for NaN in gradients
for name, param in model.named_parameters():
 if param.grad is not None:
 if torch.isnan(param.grad).any():
 print(f"NaN in gradient of {name}")
 # Option: zero out NaN gradients
 param.grad[torch.isnan(param.grad)] = 0

2. Lower learning rate
config.learning_rate = 1e-4 # From 3e-4

3. Add gradient clipping
torch.nn.utils.clip_grad_norm_(model.parameters(), max_norm=1.0)

4. Use mixed precision carefully
If using torch.amp, ensure it's configured correctly
```

### Issue 2: Loss Not Decreasing

#### Symptoms:

```

iter 0 | loss 10.4532 | lr 3.00e-04
iter 500 | loss 10.4201 | lr 3.00e-04
iter 1000 | loss 10.3987 | lr 3.00e-04
iter 2000 | loss 10.3654 | lr 3.00e-04

```

Loss decreases very slowly or not at all.

#### Causes:

1. Learning rate too low
2. Model too small for task
3. Bad initialization
4. Data problems

#### Diagnostic code:

```

def diagnose_training(model, data_batch):
 """Diagnose why training isn't working"""

 print("\n" + "="*60)
 print("TRAINING DIAGNOSTICS")
 print("="*60)

 # 1. Check data
 x, y = data_batch
 print(f"\n1. Data Check:")
 print(f" Input shape: {x.shape}")
 print(f" Target shape: {y.shape}")
 print(f" Input range: [{x.min()}, {x.max()}]")
 print(f" Unique inputs: {len(torch.unique(x))}")

 # 2. Check forward pass
 print(f"\n2. Forward Pass:")
 with torch.no_grad():
 logits, loss = model(x, y)
 print(f" Logits shape: {logits.shape}")
 print(f" Loss: {loss.item():.4f}")
 print(f" Expected random loss: {math.log(model.config['vocab_size']):.4f}")

 # 3. Check predictions
 print(f"\n3. Predictions:")
 probs = F.softmax(logits[0, 0], dim=-1)
 top5_probs, top5_indices = torch.topk(probs, 5)
 print(f" Top 5 predicted tokens: {top5_indices.tolist()}")
 print(f" Top 5 probabilities: {top5_probs.tolist()}")
 print(f" Is model just predicting same token? {len(set(torch.argmax(logits,
 ↪ dim=-1).flatten().tolist())) == 1}")

 # 4. Check gradients
 print(f"\n4. Gradient Check:")
 loss.backward()

```

```

grad_norms = {}
for name, param in model.named_parameters():
 if param.grad is not None:
 grad_norm = param.grad.norm().item()
 grad_norms[name] = grad_norm

print(f" Total gradient norm: {sum(grad_norms.values()):.4f}")
print(f" Max gradient norm: {max(grad_norms.values()):.4f}")
print(f" Min gradient norm: {min(grad_norms.values()):.4f}")

Check for vanishing gradients
if max(grad_norms.values()) < 1e-7:
 print(f" ⚠ WARNING: Gradients are very small (vanishing gradients)")

Check for exploding gradients
if max(grad_norms.values()) > 100:
 print(f" ⚠ WARNING: Gradients are very large (exploding gradients)")

print("="*60 + "\n")

Use it
diagnose_training(model, next(iter(train_loader)))

```

## Solutions:

```

1. Increase learning rate
config.learning_rate = 6e-4 # From 3e-4

2. Check model initialization
def init_weights(module):
 if isinstance(module, nn.Linear):
 torch.nn.init.normal_(module.weight, mean=0.0, std=0.02)
 if module.bias is not None:
 torch.nn.init.zeros_(module.bias)

model.apply(init_weights)

3. Verify data is not degenerate
Check that batches have variety
unique_seqs = len(set([tuple(x.tolist()) for x in train_data[:100]]))
print(f"Unique sequences in first 100: {unique_seqs}") # Should be close to 100

```

## Issue 3: Overfitting

### Symptoms:

Iteration 5000:

Train loss: 1.2341

Val loss: 1.2456

Iteration 10000:

Train loss: 0.8234

Val loss: 1.4567 ← Val loss increasing!

## Solutions:

*# 1. Increase dropout*

```
config.dropout = 0.2 # From 0.1
```

*# 2. Increase weight decay*

```
config.weight_decay = 0.3 # From 0.1
```

*# 3. Early stopping*

```
class EarlyStopping:
```

```
 def __init__(self, patience=5, min_delta=0.001):
```

```
 self.patience = patience
```

```
 self.min_delta = min_delta
```

```
 self.counter = 0
```

```
 self.best_loss = float('inf')
```

```
 def should_stop(self, val_loss):
```

```
 if val_loss < self.best_loss - self.min_delta:
```

```
 self.best_loss = val_loss
```

```
 self.counter = 0
```

```
 return False
```

```
 else:
```

```
 self.counter += 1
```

```
 if self.counter >= self.patience:
```

```
 print(f"Early stopping triggered! No improvement for {self.patience} evaluations")
```

```
 return True
```

```
 return False
```

```
early_stopping = EarlyStopping(patience=5)
```

*# In training loop*

```
if iter_num % eval_interval == 0:
```

```
 val_loss = evaluate()
```

```
 if early_stopping.should_stop(val_loss):
```

```
 break # Stop training
```

*# 4. Get more data (Chapter 4) or reduce model size (Chapter 5)*

## Issue 4: Out of Memory (OOM)

### Symptoms:

**RuntimeError:** CUDA out of memory. Tried to allocate 2.00 GiB (GPU 0; 11.91 GiB total capacity; 9.87 GiB already allocated)

### Solutions:

```
1. Reduce batch size
config.batch_size = 8 # From 12

2. Reduce context length
config.block_size = 256 # From 512

3. Use gradient accumulation
config.batch_size = 4
config.gradient_accumulation_steps = 3 # Effective batch = 12

4. Use gradient checkpointing (trades compute for memory)
from torch.utils.checkpoint import checkpoint

class CheckpointedTransformerBlock(nn.Module):
 def forward(self, x):
 # Use checkpoint to save memory
 return checkpoint(self._forward, x, use_reentrant=False)

 def _forward(self, x):
 x = x + self.attn(self.ln1(x))
 x = x + self.mlp(self.ln2(x))
 return x

5. Clear cache
torch.cuda.empty_cache()
```

## Part 6: Complete Training Pipeline

Here's the complete, production-ready training script that brings together everything from Chapters 4, 5, and 6:

NOTE: To train this model, you need to change runtime type to A100 GPU, T4 has not enough memory.

### Step 1: Data Preparation

```

"""
prepare_training_data.py - Create train.pt and val.pt
Uses data preparation techniques from Chapter 4
"""

import torch
from transformers import AutoTokenizer
import numpy as np
from datasets import load_dataset
import os

class DatasetPreparer:
 def __init__(self, tokenizer_name="gpt2", max_length=1024):
 """Initialize with tokenizer"""
 print(f"Loading tokenizer: {tokenizer_name}")
 self.tokenizer = AutoTokenizer.from_pretrained(tokenizer_name)
 self.max_length = max_length

 if self.tokenizer.pad_token is None:
 self.tokenizer.pad_token = self.tokenizer.eos_token

 def tokenize_texts(self, texts, desc="Tokenizing"):
 """Tokenize list of texts into token IDs"""
 all_tokens = []

 print(f"\n{desc}...")
 for i, text in enumerate(texts):
 if i % 1000 == 0 and i > 0:
 print(f" Processed {i}/{len(texts)} texts...")

 tokens = self.tokenizer.encode(
 text,
 max_length=self.max_length,
 truncation=True,
 add_special_tokens=True
)
 all_tokens.extend(tokens)

 print(f" Total tokens: {len(all_tokens):,}")
 return all_tokens

### This pipeline integrates:

- Chapter 4's data preparation
- Chapter 5's model configurations
- Chapter 6's production training loop

### You'll use this same pipeline for:

- Training different sized models
- MiniMind pretraining in Chapter 8
- The complete workflow through Part III

## Summary and Next Steps

### What You've Learned

You now have a production training pipeline with:

- □ Gradient accumulation (work around GPU limits)
- □ Learning rate scheduling (optimize convergence)
- □ Gradient clipping (prevent explosions)
- □ Proper weight decay (prevent overfitting)
- □ TensorBoard/WandB monitoring (know what's happening)
- □ Checkpointing and recovery (don't lose days of training)
- □ Diagnostic tools (troubleshoot issues)

## What's Coming Next

### Chapter 7: Evaluation & Benchmarks

Now that you can train models, you need to know if they're actually good! You'll learn:

- How to measure model quality (perplexity, loss)
- Downstream task evaluation
- When your model is “good enough”
- How to compare with baselines

### Part III: The MiniMind Case Study (Chapters 8-10)

After mastering training in Part II, you'll apply everything to build a complete modern SLM:

- **Chapter 8:** Pretrain MiniMind (26M-218M params) using these same training techniques
- **Chapter 9:** Supervised Fine-Tuning (SFT) with LoRA/QLoRA
- **Chapter 10:** Direct Preference Optimization (DPO)

**The training principles you learned in Chapter 6 are universal:**

- Gradient accumulation works for any model size
- Learning rate scheduling applies to pretraining, SFT, and DPO
- Checkpointing saves any long training run
- Monitoring helps with any model

Whether you're training GPT-2 (Chapters 6-7) or MiniMind (Chapters 8-10), the training loop is the same!

**Complete Code Repository:** All code from this chapter is available at Google Colab: <https://rewriting.ai/bookcode/slm.php>

### Access codes:

1, XRJAL8XJ89 2, JLZB321MLP 3, Q2GFBOQA7D  
4, 6IQ6GZW8OJ 5, 9SR5K5TJG1

**Next:** Chapter 7–Evaluation & Benchmarks: Measure if your training actually worked ->

# Chapter 7: Evaluation & Benchmarks

## Introduction: How Do You Know If Your Model Is Good?

You’ve trained your model for hours (or days). The loss dropped from 10.4 to 4.7. But is it actually good? Can you deploy it? How does it compare to alternatives?

**Loss alone doesn’t tell the full story.** A model with loss 4.7 might be terrible at your actual task, while one with loss 2.1 might be perfect for a different domain.

This chapter teaches you to:

- Interpret training and validation metrics correctly
- Evaluate on downstream tasks (the work you actually care about)
- Compare against baselines and alternatives
- Decide when your model is “good enough” to deploy

**What you’ll build:** A comprehensive evaluation suite for your models.

**Time required:** 30–45 minutes

**Prerequisites:** Chapters 4–6 (you need a trained model to evaluate)

From Chapter 6, you should have saved **“best\_model.pt”** and **“val.pt”** (and optionally **“train.pt”**). These are the files we’ll use throughout this chapter.

After loading the model and files, you will see (please check the colab notebook file):

Loading model...

✓ Model loaded: 77.2M parameters

Config: {'vocab\_size': 50257, 'n\_embd': 512, 'n\_layer': 8, 'n\_head': 8, 'block\_size': 1024,  
↪ 'dropout': 0.1}

Loading validation data...

✓ Validation data loaded: 672 samples

Loading training data (for baselines)...

✓ Training data loaded: 6050 samples

## Part 1: Understanding Perplexity

### What is Perplexity?

**Perplexity** is the standard metric for language models. It measures how “surprised” the model is by the data.

#### Mathematical definition:

$\text{Perplexity} = \exp(\text{loss})$

That’s it. If your loss is 2.5, perplexity is  $e^{2.5} \approx 12.18$ .

**Intuitive interpretation:** Perplexity of 12 means the model is as confused as if it had to randomly choose between 12 equally likely options at each step.

Let’s see this in action with our model:

```
import math

def calculate_perplexity(loss):
 """Convert loss to perplexity"""
 return math.exp(loss)

Examples
losses = [1.0, 2.0, 3.0, 4.0, 5.0]
for loss in losses:
 ppl = calculate_perplexity(loss)
 print(f"Loss: {loss:.2f} → Perplexity: {ppl:.2f}")
```

#### Output:

```
=====
UNDERSTANDING PERPLEXITY
=====
```

Loss to Perplexity conversion:

```
Loss: 1.00 → Perplexity: 2.72 → Excellent - Ready for production
Loss: 2.00 → Perplexity: 7.39 → Excellent - Ready for production
Loss: 3.00 → Perplexity: 20.09 → Excellent - Ready for production
Loss: 4.00 → Perplexity: 54.60 → Good - Acceptable for most uses
Loss: 5.00 → Perplexity: 148.41 → Poor - Significant issues
```

### What’s a Good Perplexity?

It depends on your domain:

Domain	Typical Perplexity	Interpretation
Simple text (recipes, product descriptions)	10-30	Very predictable
General English (Wikipedia)	30-50	Moderately predictable
Creative writing (fiction)	50-100	Less predictable
Highly technical (legal, scientific)	40-80	Specialized vocabulary
Random text	vocab_size	Completely unpredictable

**Rule of thumb:** Lower is better, but compare within same domain only. A perplexity of 50 on creative writing might be excellent, but the same score on recipe text suggests problems.

Here's a function to interpret perplexity for different domains:

```
def interpret_perplexity(perplexity, domain='general'):
 """Interpret perplexity score"""

 benchmarks = {
 'recipes': {'excellent': 15, 'good': 25, 'fair': 40},
 'general': {'excellent': 30, 'good': 50, 'fair': 80},
 'creative': {'excellent': 50, 'good': 80, 'fair': 120},
 'technical': {'excellent': 40, 'good': 70, 'fair': 100},
 }

 bench = benchmarks.get(domain, benchmarks['general'])

 if perplexity < bench['excellent']:
 return "Excellent - Ready for production"
 elif perplexity < bench['good']:
 return "Good - Acceptable for most uses"
 elif perplexity < bench['fair']:
 return "Fair - May need more training"
 else:
 return "Poor - Significant issues"

Example
ppl = 45
print(f"Perplexity {ppl} on general text: {interpret_perplexity(ppl, 'general')}")
```

## Part 2: Basic Evaluation Metrics

Now let's evaluate our actual trained model. We'll start with three fundamental metrics:

1. **Loss** - The raw cross-entropy loss
2. **Perplexity** - Exponentiated loss (easier to interpret)
3. **Token Accuracy** - What percentage of next tokens did we predict correctly?

## Setting Up the Evaluation

First, we need to load our trained model and validation data:

```
Load model checkpoint
print("Loading model...")
ckpt = torch.load('best_model.pt', map_location=device, weights_only=False)

if isinstance(ckpt, dict) and 'model_state_dict' in ckpt:
 state_dict = ckpt['model_state_dict']
 config = ckpt.get('config', fallback_config)
else:
 state_dict = ckpt
 config = fallback_config

model = ConfigurableGPT(config)
model.load_state_dict(state_dict, strict=False)
model.to(device).eval()

Load validation data
val_data = torch.load('val.pt', map_location='cpu')
val_dataset = ValTensorDataset(val_data)
val_loader = DataLoader(val_dataset, batch_size=32, shuffle=False)
```

### Output:

```
Loading model...
Model initialized with 77.2M parameters
✔ Model loaded: 77.2M parameters
 Config: {'vocab_size': 50257, 'n_embd': 512, 'n_layer': 8, 'n_head': 8,
 'block_size': 1024, 'dropout': 0.1, 'batch_size': 32}

Loading validation data...
✔ Validation data loaded: 672 samples
```

## Running Basic Evaluation

Now let's compute our three basic metrics:

```

@torch.no_grad()
def evaluate_basic(model, dataloader, device):
 """
 Evaluate model on loss, perplexity, token-level accuracy
 using next-token prediction.
 """
 model.eval()

 total_loss = 0.0
 total_correct = 0
 total_tokens = 0

 for batch in dataloader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
 x = x.to(device)
 if x.dim() == 1:
 x = x.unsqueeze(0)

 # Next-token targets; ignore last token at each row
 y = x.clone()
 y[:, :-1] = x[:, 1:]
 y[:, -1] = -1 # ignored in loss

 logits, loss = model(x, y)
 total_loss += loss.item()

 preds = torch.argmax(logits, dim=-1)
 mask = (y != -1)
 correct = (preds[mask] == y[mask]).sum().item()
 total_correct += correct
 total_tokens += mask.sum().item()

 avg_loss = total_loss / max(len(dataloader), 1)
 perplexity = math.exp(avg_loss) if avg_loss < 20 else float('inf')
 accuracy = total_correct / total_tokens if total_tokens > 0 else 0.0

 return {
 'loss': avg_loss,
 'perplexity': perplexity,
 'accuracy': accuracy,
 'total_tokens': total_tokens,
 }

Run evaluation
basic_results = evaluate_basic(model, val_loader, device)

```

**Output:**

---

**BASIC EVALUATION RESULTS**

---

 Loss: 4.7098  
 Perplexity: 111.05  
 Token Accuracy: 27.27%  
 Total Tokens Evaluated: 687,456

 Interpretation: Fair - May need more training

## Understanding the Results

Let's break down what these numbers mean:

### Loss: 4.71

- This is the raw cross-entropy loss
- Lower is better
- For general text, we'd want this closer to 2.0-3.0

### Perplexity: 111.05

- The model is as confused as randomly picking between ~111 options
- For general English text, good models achieve 30-50
- Our model needs more training

### Token Accuracy: 27.27%

- We correctly predict the next token 27% of the time
- For comparison:
  - Random guessing: ~0.002% (1 in 50,257 tokens)
  - Good models: 40-60%
  - State-of-the-art: 70-80%

**Warning:** Our model is performing fairly poorly (27% accuracy, perplexity 111). This suggests we need more training data, more epochs, or better hyperparameters. However, this gives us a great baseline to improve from!

## Part 3: Advanced Metrics

Basic metrics don't tell the whole story. Let's dig deeper with advanced metrics that reveal model behavior:

1. **Sequence Accuracy** - How often do we get an entire sequence perfectly right?
2. **Confidence Analysis** - How accurate is the model when it's confident vs. uncertain?

### Implementing Advanced Evaluation

```
@torch.no_grad()
def evaluate_advanced(model, dataloader, device):
 """Advanced evaluation with confidence analysis"""
 model.eval()

 total_correct = 0
 total_tokens = 0
 perfect_sequences = 0
 total_sequences = 0

 high_conf_correct = 0
 high_conf_total = 0
 low_conf_correct = 0
 low_conf_total = 0

 confidence_threshold = 0.8

 for batch in dataloader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
 x = x.to(device)
 if x.dim() == 1:
 x = x.unsqueeze(0)

 y = x.clone()
 y[:, :-1] = x[:, 1:]
 y[:, -1] = -1

 logits, _ = model(x, y)
 probs = F.softmax(logits, dim=-1)
 preds = torch.argmax(logits, dim=-1)

 mask = (y != -1)
 correct_per_token = (preds == y) & mask

 # Token accuracy
 total_correct += correct_per_token.sum().item()
 total_tokens += mask.sum().item()

 # Sequence accuracy
 for i in range(x.size(0)):
 seq_mask = mask[i]
```

```

 if seq_mask.sum() > 0:
 if correct_per_token[i][seq_mask].all():
 perfect_sequences += 1
 total_sequences += 1

 # Confidence analysis
 max_probs = probs.max(dim=-1)[0]
 high_conf_mask = (max_probs > confidence_threshold) & mask
 low_conf_mask = (max_probs <= confidence_threshold) & mask

 if high_conf_mask.any():
 high_conf_correct += correct_per_token[high_conf_mask].sum().item()
 high_conf_total += high_conf_mask.sum().item()

 if low_conf_mask.any():
 low_conf_correct += correct_per_token[low_conf_mask].sum().item()
 low_conf_total += low_conf_mask.sum().item()

 return {
 'token_accuracy': total_correct / max(total_tokens, 1),
 'sequence_accuracy': perfect_sequences / max(total_sequences, 1),
 'confidence_analysis': {
 'precision_high_confidence': high_conf_correct / max(high_conf_total, 1),
 'precision_low_confidence': low_conf_correct / max(low_conf_total, 1),
 'high_confidence_count': high_conf_total,
 'low_confidence_count': low_conf_total,
 }
 }

Run advanced evaluation
advanced_results = evaluate_advanced(model, val_loader, device)

```

## Output:

```

=====
ADVANCED EVALUATION RESULTS
=====

```

 Token Accuracy: 27.27%  
 Sequence Accuracy: 0.00%  
 (What % of entire sequences were predicted perfectly)

 Confidence Analysis:  
 When model **is** CONFIDENT (>80% probability):  
 - Accuracy: 78.95%  
 - Count: 142,308 tokens

When model **is** UNCERTAIN (≤80% probability):  
 - Accuracy: 14.73%  
 - Count: 545,148 tokens

 When your model **is** confident, it's usually right! This is a good sign.

## Interpreting Advanced Metrics

### Sequence Accuracy: 0.00%

- Not a single complete sequence was predicted perfectly
- This is actually **normal** for undertrained models
- Even with 27% token accuracy, getting all ~1000 tokens right in a row is nearly impossible
- Good models might achieve 1-5% sequence accuracy

### Confidence Analysis - The Key Insight:

This is where things get interesting! Our model shows **strong calibration**:

- **When confident (>80% probability):** 78.95% accuracy
- **When uncertain (≤80% probability):** 14.73% accuracy

**What this means:** Our model “knows what it knows”! When it’s confident, it’s usually right. When it’s uncertain, it makes many errors. This is excellent behavior – it means the model isn’t overconfident in its mistakes.

This confidence analysis is crucial for production systems:

```
In production, you could use confidence to decide actions:
if confidence > 0.8:
 # Trust the prediction
 return predicted_token
else:
 # Flag for human review or use fallback
 return fallback_option
```

## Part 4: Comparing Against Baselines

**Always compare against baselines.** Your 27% accuracy might seem low, but how does it compare to simpler approaches?

We’ll evaluate three baselines:

1. **Random Selection** – What if we randomly guessed tokens?
2. **Most Frequent Token** – What if we always predicted the most common token?
3. **3-gram Model** – What if we used a simple n-gram model?

### Baseline 1: Random Selection

```
def random_baseline(dataloader, vocab_size):
 """Evaluate random token selection baseline"""
 correct = 0
 total = 0

 for batch in dataloader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
 y = x.clone()
 y[:, :-1] = x[:, 1:]
 y[:, -1] = -1

 mask = (y != -1)
 random_preds = torch.randint(0, vocab_size, y.shape)
 correct += ((random_preds == y) & mask).sum().item()
 total += mask.sum().item()

 accuracy = correct / max(total, 1)
 return {'accuracy': accuracy, 'perplexity': vocab_size}

Evaluate
random_results = random_baseline(val_loader, config['vocab_size'])
```

## Output:

```
1 Random Selection Baseline
Accuracy: 0.0019%
Perplexity: ~50257
```

**Analysis:** Random guessing gives ~0.002% accuracy. Our model's 27% is **14,000x better** than random!

## Baseline 2: Most Frequent Token

```
def most_frequent_baseline(train_loader, test_loader):
 """Always predict the most frequent token"""

 # Find most frequent token in training data
 all_tokens = []
 for batch in train_loader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
 all_tokens.extend(x.flatten().tolist())

 token_counts = Counter(all_tokens)
 most_frequent = token_counts.most_common(1)[0][0]

 # Evaluate on test data
 correct = 0
 total = 0

 for batch in test_loader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
```

```

y = x.clone()
y[:, :-1] = x[:, 1:]
y[:, -1] = -1

mask = (y != -1)
correct += (y[mask] == most_frequent).sum().item()
total += mask.sum().item()

accuracy = correct / max(total, 1)
return {'accuracy': accuracy, 'most_frequent_token': most_frequent}

Evaluate
freq_results = most_frequent_baseline(train_loader, val_loader)

```

## Output:

```

20 Most Frequent Token Baseline
Accuracy: 3.45%
(Always predicts token #220)

```

**Analysis:** Always predicting the most frequent token gives 3.45% accuracy. Our model is **7.9x better** than this naive approach.

## Baseline 3: N-gram Model

```

class NgramModel:
 """Simple n-gram language model baseline"""

 def __init__(self, n=3):
 self.n = n
 self.counts = defaultdict(Counter)

 def train(self, dataloader):
 """Train on sequences"""
 for batch in dataloader:
 x = batch[0] if isinstance(batch, (tuple, list)) else batch
 if len(x.shape) == 2:
 for seq in x:
 self._train_sequence(seq.tolist())
 else:
 self._train_sequence(x.tolist())

 def _train_sequence(self, tokens):
 """Train on single sequence"""
 for i in range(len(tokens) - self.n):
 context = tuple(tokens[i:i+self.n-1])
 next_token = tokens[i+self.n-1]
 self.counts[context][next_token] += 1

 def predict(self, context):

```

```

 """Predict next token given context"""
 context = tuple(context[-(self.n-1):])
 if context in self.counts and len(self.counts[context]) > 0:
 return self.counts[context].most_common(1)[0][0]
 else:
 if len(context) > 1:
 return self.predict(list(context[1:]))
 else:
 return 0

 def evaluate(self, dataloader):
 """Evaluate on test data"""
 # ... evaluation code ...
 return accuracy

Train and evaluate
ngram = NgramModel(n=3)
ngram.train(train_loader)
ngram_acc = ngram.evaluate(val_loader)

```

### Output:

```

3█ 3-gram Model Baseline
 Training 3-gram model... (this may take a minute)
 Accuracy: 12.34%

```

**Analysis:** A simple 3-gram model achieves 12.34% accuracy. Our neural model is **2.2x better** than this traditional NLP approach.

## Baseline Comparison Summary

### COMPARISON SUMMARY

Your Model:	27.27%
Random:	0.0019%
Most Frequent:	3.45%
3-gram:	12.34%

✅ SUCCESS! Your model is 121.1% better than best baseline

**Key Insight:** Our model significantly outperforms all baselines, which confirms that our neural network is learning meaningful patterns. However, there's still room for improvement - good models should achieve 40-60% token accuracy.

## Part 5: Text Generation Quality

Accuracy metrics are important, but what really matters is: **Can the model generate good text?**

Let's evaluate generation quality with two metrics:

1. **Repetition Score** - How repetitive is the generated text? (lower is better)
2. **Diversity Score** - How varied is the vocabulary? (higher is better)

### Implementing Text Generation

```
@torch.no_grad()
def generate_text_simple(model, start_tokens, max_new_tokens=50,
 temperature=0.8, device='cuda'):
 """Simple text generation"""
 model.eval()
 tokens = start_tokens.clone().to(device)

 for _ in range(max_new_tokens):
 logits, _ = model(tokens.unsqueeze(0), None)
 logits = logits[0, -1, :] / temperature
 probs = F.softmax(logits, dim=-1)
 next_token = torch.multinomial(probs, 1)
 tokens = torch.cat([tokens, next_token], dim=0)

 if tokens.size(0) >= model.config['block_size']:
 break

 return tokens

def calculate_repetition(tokens):
 """Measure repetitiveness using bigrams"""
 if len(tokens) < 2:
 return 0.0

 bigrams = [(tokens[i], tokens[i+1]) for i in range(len(tokens)-1)]
 unique_bigrams = len(set(bigrams))
 total_bigrams = len(bigrams)

 repetition = 1.0 - (unique_bigrams / total_bigrams)
 return repetition

def calculate_diversity(tokens):
 """Measure vocabulary diversity"""
 if len(tokens) == 0:
 return 0.0

 unique_tokens = len(set(tokens))
 total_tokens = len(tokens)

 return unique_tokens / total_tokens
```

## Evaluating Generated Text

```
Generate multiple samples
num_samples = 5
generation_results = []

for i in range(num_samples):
 # Get random starting sequence from validation data
 sample_idx = random.randint(0, len(val_loader.dataset) - 1)
 start_seq = val_loader.dataset[sample_idx]
 start_tokens = start_seq[:10]

 # Generate continuation
 generated = generate_text_simple(model, start_tokens,
 max_new_tokens=50, device=device)
 tokens_list = generated.tolist()

 # Compute quality metrics
 repetition = calculate_repetition(tokens_list)
 diversity = calculate_diversity(tokens_list)

 generation_results.append({
 'sample_id': i + 1,
 'length': len(tokens_list),
 'repetition_score': repetition,
 'diversity_score': diversity,
 })

Compute averages
avg_repetition = sum(r['repetition_score'] for r in generation_results) / len(generation_results)
avg_diversity = sum(r['diversity_score'] for r in generation_results) / len(generation_results)
```

### Output:

```
=====
TEXT GENERATION QUALITY
=====

Generating sample texts and evaluating quality...

📊 Average Repetition: 7.46% (lower is better)
📊 Average Diversity: 70.33% (higher is better)

💡 Quality Assessment:
✅ Good generation quality - diverse and not repetitive
```

## Understanding Generation Metrics

**Repetition Score: 7.46%**

- Measures how often we see repeated bigrams (two-token sequences)
- 7.46% means about 93% of bigrams are unique
- Good models: 5-15%
- Bad models (overfitting): >30%

### Diversity Score: 70.33%

- Measures vocabulary variety (unique tokens / total tokens)
- 70.33% means the model uses a varied vocabulary
- Good models: 60-80%
- Bad models (mode collapse): <40%

**Tip:** These generation metrics complement accuracy metrics. A model can have low accuracy but generate fluent text, or vice versa. Both are important for understanding model quality.

## Part 6: Model Readiness Check

Now comes the critical question: **Is your model ready for deployment?**

Let's create a systematic way to decide based on objective criteria.

### Defining Requirements

First, define what “ready” means for your use case:

```
class ModelReadinessChecker:
 """Determine if model is ready for deployment"""

 def __init__(self, requirements):
 """
 requirements: dict with minimum thresholds
 Example:
 {
 'min_accuracy': 0.30,
 'max_perplexity': 150,
 'min_sequence_accuracy': 0.05,
 }
 """
 self.requirements = requirements

 def check_readiness(self, basic_metrics, advanced_metrics=None):
 """Check if model meets requirements"""
 checks = {}

 # Check accuracy
```

```

if 'min_accuracy' in self.requirements:
 checks['accuracy'] = (
 basic_metrics.get('accuracy', 0) >=
 self.requirements['min_accuracy']
)

Check perplexity
if 'max_perplexity' in self.requirements:
 checks['perplexity'] = (
 basic_metrics.get('perplexity', float('inf')) <=
 self.requirements['max_perplexity']
)

Check sequence accuracy
if advanced_metrics and 'min_sequence_accuracy' in self.requirements:
 checks['sequence_accuracy'] = (
 advanced_metrics.get('sequence_accuracy', 0) >=
 self.requirements['min_sequence_accuracy']
)

is_ready = all(checks.values()) if checks else False
report = self._generate_report(checks, basic_metrics, advanced_metrics)

return is_ready, report

```

## Running the Readiness Check

```

Define requirements (customize for your use case)
requirements = {
 'min_accuracy': 0.30, # Minimum token accuracy
 'max_perplexity': 150, # Maximum perplexity
 'min_sequence_accuracy': 0.05, # Minimum sequence accuracy
}

checker = ModelReadinessChecker(requirements)
is_ready, report = checker.check_readiness(basic_results, advanced_results)

```

### Output:

```
=====
MODEL READINESS REPORT
=====
```

## Requirement Checks:

```
accuracy: ❌ FAIL
perplexity: ✅ PASS
sequence_accuracy: ❌ FAIL
```

## Current Metrics:

```
Accuracy: 27.27%
Perplexity: 111.05
Sequence Accuracy: 0.00%
```

## Recommendation:

```
❌ Model needs MORE TRAINING
Failed checks: accuracy, sequence_accuracy
```

```
=====
```

## Understanding the Results

Our model **fails** the readiness check because:

1. **Accuracy (27.27%) < Minimum Required (30%)**
  - We're close! Just 2.73 percentage points away
  - A bit more training should get us there
2. **Sequence Accuracy (0.00%) < Minimum Required (5%)**
  - This is expected for an undertrained model
  - Sequence accuracy is very difficult to achieve
3. **Perplexity (111.05) < Maximum Allowed (150) □**
  - This requirement is met
  - Our perplexity is acceptable, though not great

### Decision: More Training Needed

Based on our systematic evaluation, this model should NOT be deployed yet. The good news: we're close! With more training (additional epochs, more data, or hyperparameter tuning), we can likely reach deployment quality.

## Part 7: Complete Evaluation Summary

Let's save all our results for future reference:

```

all_results = {
 'basic_metrics': basic_results,
 'advanced_metrics': advanced_results,
 'generation_quality': {
 'average_repetition': avg_repetition,
 'average_diversity': avg_diversity,
 'samples': generation_results
 },
 'baseline_comparisons': {
 'random': random_results,
 'most_frequent': freq_results,
 'ngram_3': {'accuracy': ngram_acc}
 },
 'model_config': config,
 'is_ready_for_deployment': is_ready,
}

Save to JSON
with open('chapter7_evaluation_results.json', 'w') as f:
 json.dump(all_results, f, indent=2)

print("✅ Results saved to chapter7_evaluation_results.json")

```

## Final Summary:

=====

CHAPTER 7 COMPLETE! 🎉

=====

### Summary of Your Model:

- Perplexity: 111.05
- Token Accuracy: 27.27%
- Sequence Accuracy: 0.00%
- Generation Quality: Repetition 7.46%, Diversity 70.33%

⚠️ Your model needs more training to meet requirements.

### What You Learned:

- ✓ How to interpret perplexity
- ✓ Basic **and** advanced evaluation metrics
- ✓ Comparing against baselines
- ✓ Evaluating text generation quality
- ✓ Determining model readiness

### 🎯 Next Steps:

1. Review your evaluation results
  2. If **not** ready: adjust training (more data, longer training, tune hyperparameters)
  3. If ready: proceed to Chapter 8 (Advanced Fine-Tuning **with** LoRA)
- =====

## Key Takeaways

After completing this chapter, you should understand:

### Metrics and Their Meaning

1. **Perplexity =  $\exp(\text{loss})$**  - Standard metric, but domain-dependent
  - Lower is better
  - Compare only within the same domain
  - Our model: 111.05 (fair, needs improvement)
2. **Token Accuracy** - Percentage of correctly predicted next tokens
  - Our model: 27.27%
  - Good models: 40-60%
  - SOTA: 70-80%
3. **Sequence Accuracy** - Percentage of perfectly predicted sequences
  - Our model: 0.00% (expected for undertrained models)
  - Good models: 1-5%
  - Very difficult metric to optimize
4. **Confidence Analysis** - Accuracy when confident vs. uncertain
  - Our model shows good calibration (78.95% when confident, 14.73% when uncertain)
  - This is excellent behavior - the model “knows what it knows”

### Baseline Comparisons Matter

Always compare against baselines:

- Random: 0.002% accuracy
- Most frequent: 3.45% accuracy
- 3-gram: 12.34% accuracy
- **Our model: 27.27% accuracy** □

If you can't beat simple baselines, something is wrong with your training!

## Generation Quality Complements Accuracy

Two key metrics:

- **Repetition score:** 7.46% (lower is better) □
- **Diversity score:** 70.33% (higher is better) □

Our model generates diverse, non-repetitive text, which is encouraging!

## Systematic Deployment Decisions

Define objective criteria before training:

- Minimum accuracy threshold
- Maximum perplexity threshold
- Minimum sequence accuracy (if applicable)

Then make data-driven decisions about deployment.

## Common Pitfalls to Avoid

### 1. Only looking at loss

- Loss can be misleading
- Always evaluate on actual tasks

### 2. No baseline comparison

- Your 75% accuracy might sound good
- But if a simple baseline gets 80%, your model has issues

### 3. Overfitting to test set

- Don't tune hyperparameters based on test set performance
- Use a separate validation set

### 4. Ignoring failure modes

- A model that works 95% of the time but fails catastrophically 5% of the time is not production-ready
- Use confidence analysis to catch these cases

### 5. No human evaluation

- Metrics can't capture everything
- Have humans review outputs before deployment

## What's Next

You've completed Phase 2: Understanding the Fundamentals.

You now know how to:

- Prepare datasets (Chapter 4)
- Configure architectures (Chapter 5)
- Train models (Chapter 6)
- **Evaluate results (Chapter 7)** □

## Next Phase: Advanced Techniques

In Chapter 8, you'll learn efficient fine-tuning with LoRA and QLoRA - techniques that let you adapt pre-trained models to your specific task with:

- 10x less memory
- 10x faster training
- Similar or better performance

## Improving Your Current Model

If your model didn't pass the readiness check (like ours), here's what to try:

### 1. More Training

- Increase epochs from 10 to 20-30
- Continue training from your current checkpoint

### 2. More Data

- Increase NUM\_SAMPLES in data preparation
- Add more diverse data sources

### 3. Better Hyperparameters

- Try different learning rates
- Adjust model size (more layers, more heads)
- Tune dropout rates

### 4. Better Architecture

- Add more transformer blocks
- Increase embedding dimensions
- Try different attention mechanisms

After making improvements, re-run this evaluation notebook to measure progress!

**Pro Tip:** Keep a log of all your evaluation results. Track how changes to training affect your metrics. This lets you make informed decisions about what works and what doesn't.

## Evaluation Checklist

When evaluating your model, make sure you've completed:

- ☐ **Basic metrics computed:** Loss, perplexity, token accuracy
- ☐ **Advanced metrics analyzed:** Sequence accuracy, confidence analysis
- ☐ **Compared against baselines:** Random, most frequent, n-gram
- ☐ **Generation quality tested:** On relevant prompts
- ☐ **Readiness check passed:** All requirements met
- ☐ **Results documented:** Saved evaluation\_results.json

## Summary

In this chapter, you learned a complete evaluation framework:

1. **Understanding Perplexity** - The standard metric for language models
2. **Basic Evaluation** - Loss, perplexity, and token accuracy
3. **Advanced Metrics** - Sequence accuracy and confidence analysis
4. **Baseline Comparisons** - Always compare against simple approaches
5. **Generation Quality** - Evaluate actual generated text
6. **Readiness Check** - Systematic deployment decisions
7. **Complete Documentation** - Save results for future reference

You now have professional-grade tools to evaluate any language model!

**Complete Code Repository:** All code from this chapter is available at:

<https://rewriting.ai/bookcode/slm.php>

**Access codes:**

1, F1GLCFXY3U 2, B69B4KNGEE 3, 21SJWIZKA8  
4, VDJ0GTE12T 5, F7CDMQ0G8Z

**Next:** Chapter 8 - Stage 1 MiniMind pretraining ->

# Chapter 8: Stage 1 - Pre-train Your Own Language Model from Scratch

## Introduction: The Joy of Building from Zero

In Chapters 4-7, you learned the fundamentals: preparing datasets, configuring architectures, training models, and evaluating results. You've worked with small models on focused datasets, understanding every component from tokenization to perplexity.

**Now comes the exciting part: training a real language model from scratch.**

Not just fine-tuning a pre-trained model. Not just running inference. Not just using high-level APIs that abstract everything away. **Building from zero.**

This chapter introduces you to **MiniMind** - an educational project that makes training language models from scratch accessible to everyone.

## What is MiniMind?

**MiniMind** is an open-source project by Jingyao Gong that enables anyone to train a complete language model from scratch with minimal resources:

- 🕒 **Time:** 2-3 hours
- 💰 **Cost:** < \$5 USD in GPU rental
- 🔧 **Hardware:** Single NVIDIA 3090 (or Google Colab with free T4)
- 📦 **Parameters:** 26M to 350M (compared to billions in GPT-4)
- 🎓 **Goal:** Educational - understand every line of code

[github.com/jingyaogong/minimind/blob/master/README\\_en.md](https://github.com/jingyaogong/minimind/blob/master/README_en.md)

### MiniMind's Philosophy:

*"Building a plane with Lego bricks is far more exciting than flying in first class!"*

The project believes that truly understanding LLMs requires hands-on building, not just using pre-packaged tools.

## The Problem MiniMind Solves

Modern LLMs like ChatGPT, DeepSeek, and GPT-4 are impressive but:

### Massive Scale Makes Them Inaccessible:

- Hundreds of billions of parameters
- Impossible to train on personal hardware
- Even deployment requires specialized infrastructure

### 99% of Learning Stops at Fine-Tuning:

- Most tutorials only cover LoRA fine-tuning
- You learn to teach the model new tasks
- But you never understand how the model actually works
- *“Like teaching Newton to use a smartphone - interesting, but completely missing the point”*

### High-Level APIs Hide Everything:

- Libraries like `transformers` + `trl` are powerful
- But 10 lines of code abstract away all the magic
- You never see the core algorithms
- *“Like a spaceship that takes you places but never shows you the engine”*

### The Internet is Full of Shallow Tutorials:

- Expensive paid courses with superficial content
- Marketing accounts selling incomplete knowledge
- Copy-paste code without understanding

## MiniMind’s Solution

MiniMind lowers the barrier to entry by letting you train an extremely small but functional language model from scratch, with costs under 3 RMB (about \$0.50 USD) in GPU server rental.

### Key Features:

#### 1. Pure PyTorch Implementation

- Zero dependencies on high-level abstraction libraries
- Every algorithm coded from scratch
- No magic black boxes

## 2. Complete Pipeline

- Data preprocessing
- Tokenizer training
- Model pretraining
- Supervised fine-tuning (SFT)
- Reinforcement learning from AI feedback (RLAIF)

## 3. Multiple Model Sizes

- **MiniMind-26M**: 26M parameters, 1-2 hours training
- **MiniMind-109M**: 109M parameters, 2-3 days training
- **MiniMind-350M**: 350M parameters, ~1 week training

## 4. Educational Focus

- Every line of code is meant to be read and understood
- Comprehensive comments explaining design choices
- Step-by-step tutorials for each stage

## 5. Multimodal Extension

- **MiniMind-V**: Vision-language model variant
- Adds image understanding capabilities
- Same minimalist philosophy

## Why “Mini”?

The smallest MiniMind variant has only 25.8M (0.02B) parameters but is capable of fluent conversation.

Compare this to commercial models:

Model	Parameters	Training Cost	Personal Training?
<b>MiniMind-26M</b>	26 million	< \$5	✓ Yes - 2 hours
GPT-2	1.5 billion	~\$50K	⚠ Difficult
GPT-3	175 billion	~\$5M	✗ Impossible
GPT-4	>1 trillion	Unknown	✗ Impossible

### The Magic of Small Models:

While MiniMind can't compete with GPT-4 on complex reasoning, it demonstrates that:

- Language modeling works at small scales
- The architecture is what matters, not just size
- You can understand and modify every component
- Training from scratch is achievable for individuals

## What You'll Build in This Chapter

**Chapter 8 is divided into two stages:**

### Stage 1: Pretraining (This Chapter)

Train a language model from random initialization using large-scale text data:

**Input:** Raw English text (Wikipedia, OpenWebText)

- ~3-5 GB of text data
- 500M - 1B tokens after tokenization

**Process:**

1. Download and clean English dataset
2. Train a custom BPE tokenizer
3. Tokenize and prepare training data
4. Train the base model for 100K steps
5. Evaluate language modeling capabilities

**Output:** A pretrained language model that:

- Understands English grammar and syntax
- Can complete sentences
- Has learned basic world knowledge
- Perplexity: 10-20 (depending on size)

**Time:** 2-3 days for MiniMind-109M

### Stage 2: Instruction Tuning (Chapter 9)

Fine-tune the pretrained model to follow instructions:

**Input:** Pretrained model + instruction dataset

- Question-answer pairs
- Chat conversations
- Task demonstrations

**Output:** A chatbot that:

- Responds to questions naturally
- Follows instructions
- Maintains context in conversations
- Behaves helpfully and safely

**Time:** 4-6 hours

## How This Differs from Previous Chapters

In Chapters 4-7, you worked with:

-  Small focused datasets (recipes, specific domains)
-  Short sequences (256-512 tokens)
-  Simple training (10-20 epochs)
-  Quick experimentation (hours)

In Chapter 8-9, you'll work with:

-  Large general datasets (billions of tokens)
-  Longer sequences (512-1024 tokens)
-  Extended training (100K+ steps)
-  Multi-day experiments (days to weeks)

This is the difference between **learning** and **building a real model**.

## Key Adaptations for English

The original MiniMind was designed for Chinese. We've adapted it for English:

Aspect	Chinese (Original)	English (Adapted)
<b>Dataset</b>	Chinese Wikipedia	OpenWebText / English Wikipedia
<b>Vocab Size</b>	6,400 tokens	32,000 tokens
<b>Tokenizer</b>	BPE with NFC normalization	BPE with NFD + lowercase
<b>Compression</b>	~2-3 chars/token	~4-5 chars/token
<b>Test Prompts</b>	Chinese text	English text

English actually has **better compression** - we get more efficient tokenization!

## Prerequisites

Before starting this chapter, you should have:

-  Completed Chapters 4-7 (or equivalent knowledge)
-  Understanding of:
  - Tokenization and vocabulary

- Transformer architecture
- Training loops and optimization
- Evaluation metrics (loss, perplexity)
-  Access to:
  - Google Colab (A100 GPU works, free T4 doesn't work) or you can use A100, H100 or H200 via your HPC system.
  - OR local GPU with 24GB+ VRAM
  - 20-30 GB free disk space

## What You'll Learn

By the end of this chapter, you'll know how to:

### 1. Prepare Large-Scale Training Data

- Download and clean multi-GB text corpora
- Filter and validate data quality
- Prepare efficient training formats

### 2. Train a Custom Tokenizer

- Build a BPE tokenizer from scratch
- Choose optimal vocabulary size
- Balance compression vs. coverage

### 3. Implement Modern Training Techniques

- Rotary Position Embeddings (RoPE)
- Grouped Query Attention (GQA)
- RMSNorm instead of LayerNorm
- SwiGLU feed-forward networks

### 4. Scale Training Efficiently

- Learning rate schedules (warmup + cosine decay)
- Gradient clipping and stabilization
- Checkpointing and resuming
- Memory optimization

### 5. Monitor and Debug Training

- Track loss curves
- Detect overfitting early
- Handle OOM errors
- Optimize throughput

## The MiniMind Architecture

MiniMind uses a **decoder-only Transformer** architecture similar to GPT, with modern improvements:

### Core Components

#### 1. Tokenization

- Custom BPE tokenizer
- Vocabulary: 6,400 (Chinese) or 32,000 (English)
- Special tokens: <pad>, <unk>, <s>, </s>

#### 2. Embeddings

- Token embeddings: Map token IDs to vectors
- No positional embeddings (uses RoPE instead)
- Dimension: 512 (26M), 768 (109M), or 1024 (350M)

#### 3. Transformer Blocks

- RMSNorm (more stable than LayerNorm)
- Multi-head attention with RoPE
- SwiGLU feed-forward (better than ReLU)
- Residual connections

#### 4. Output Head

- Linear projection to vocabulary
- Weight tying with input embeddings
- Softmax for next-token prediction

### Modern Techniques

#### Rotary Position Embeddings (RoPE)

- Encodes position information into attention
- Better extrapolation to longer sequences
- No learned position embeddings needed

#### Grouped Query Attention (GQA)

- Reduces KV cache memory
- Fewer key-value heads than query heads
- Speeds up inference with minimal accuracy loss

### RMSNorm

- Simpler than LayerNorm
- No learnable bias term
- More stable training

### SwiGLU Activation

- $\text{SwiGLU}(x) = \text{Swish}(W1 \cdot x) \otimes (W2 \cdot x)$
- Better than ReLU or GELU
- Used in PaLM, LLaMA

### Model Variants

Model	Parameters	Layers	Hidden Dim	Heads	KV Heads	Training Time
<b>MiniMind-26M</b>	26M	8	512	8	4	1 day
<b>MiniMind-109M</b>	109M	16	768	16	8	2-3 days
<b>MiniMind-350M</b>	350M	24	1024	16	8	1 week

If you want to follow the Minimind's original setup, you can download

1) their model and configuration:

[github.com/jingyaogong/minimind/blob/master/README\\_en.md](https://github.com/jingyaogong/minimind/blob/master/README_en.md)

2) their pretraining and fine-tune dataset from:

[https://huggingface.co/internlm/internlm2-1\\_8b-reward/tree/main](https://huggingface.co/internlm/internlm2-1_8b-reward/tree/main)

For this chapter, we'll focus on **MiniMind-109M-like** as it offers the best balance of:

- Training time (2-3 days is manageable)
- Model quality (good conversational ability)
- Resource requirements (works on single 3090 or Colab)

## Expected Results

After completing this chapter, your model will:

### Language Modeling Capabilities:

- Perplexity: 10–20 on validation data
- Token accuracy: 40–60%
- Can complete sentences coherently

### Generation Examples:

Prompt: "The quick brown fox"

Model: "The quick brown fox jumps over the lazy dog and runs through the forest, searching **for** food."

Prompt: "In the year 2024,"

Model: "In the year 2024, artificial intelligence had become an integral part of daily life, transforming how people work **and** communicate."

### Reality Check:

Your pretrained model will NOT be a chatbot yet. It will:

- Complete sentences fluently
- Generate grammatically correct text
- Show some world knowledge
- Not follow instructions
- Not answer questions directly
- Not maintain conversational context

That's what Stage 2 (Instruction Tuning) is for!

## Chapter Structure

The rest of this chapter follows the complete pretraining pipeline:

### Part 1: Data Preparation (30 minutes)

- Download English dataset (OpenWebText)
- Clean and validate text quality
- Filter bad examples

## Part 2: Tokenizer Training (45 minutes)

- Train BPE tokenizer from scratch
- Test compression and coverage
- Save for model training

## Part 3: Dataset Creation (10 minutes)

- Convert text to JSONL format
- Tokenize all data
- Create train/validation splits

## Part 4: Model Training (2-3 days)

- Initialize model from scratch
- Train for 100K steps
- Monitor loss and generate samples

## Part 5: Evaluation and Analysis (1 hour)

- Compute perplexity
- Test generation quality
- Compare to baselines
- Analyze what the model learned

## Getting Started

Let's begin! Make sure you have:

- ☐ Google Colab account (or local GPU)
- ☐ 10-20 GB free disk space
- ☐ 2-3 days of training time available
- ☐ Chapters 4-7 completed
- ☐ Excitement about building something real! 🚀

**A Note on Training Time:**

Training for 2-3 days might seem long, but remember:

- You can pause and resume anytime
- The model saves checkpoints every 5K steps
- You'll see progress after just a few hours
- The learning experience is worth it!

As the MiniMind philosophy says: *“Building is more exciting than flying!”*

\*   \*   \*

## ##Pretraining MiniMind on English - Introduction:

**Goal:** Train a base language model from scratch using unsupervised learning on raw text.

### What is Pretraining?

Pretraining is the first phase of training a language model:

- **Input:** Massive amounts of raw text (Wikipedia, books, web pages)
- **Task:** Predict the next token given previous tokens
- **Output:** A model that understands language structure and patterns

This is called “unsupervised learning” because we don’t need labeled data - the text itself provides supervision through next-token prediction.

### Why Pretraining Matters

As MiniMind’s creator explains, the vast majority of LLM learning stops at fine-tuning existing models with LoRA, never experiencing the complete process of training from zero.

### Pretraining vs. Fine-Tuning:

Aspect	Pretraining	Fine-Tuning
<b>Data</b>	Raw text (no labels)	Labeled examples
<b>Scale</b>	Billions of tokens	Thousands of examples
<b>Goal</b>	Learn language	Learn specific behavior
<b>Cost</b>	High (days/weeks)	Low (hours)
<b>Result</b>	Base model	Specialized model

### What the model learns during pretraining:

- Grammar and syntax rules
- Vocabulary and word relationships
- Common phrases and expressions
- Basic reasoning patterns
- World knowledge (from training data)
- Text structure and formatting

## The Training Process

### Time breakdown:

- Data preparation: 30 minutes
- Tokenizer training: 45 minutes
- Data tokenization: 10 minutes
- Model training: 2-3 days
- Evaluation: 1 hour

**Total: ~2-3 days**

## Part 1: Data Preparation

### Step 1: Understanding the Dataset

We'll use **OpenWebText** - an open-source recreation of GPT-2's training data:

#### Dataset Statistics:

- **Source:** Reddit submissions with 3+ karma
- **Size:** ~40 GB raw, ~8M documents
- **Quality:** Web-scraped, needs cleaning
- **License:** Open-source, free to use

#### Why OpenWebText?

1. Diverse content (many topics and styles)
2. High-quality text (curated by human votes)
3. Easy to download (via Hugging Face)
4. Good for English pretraining

## Step 2: Download the Dataset

We'll download a 3-5 GB subset (enough for educational purposes):

```
from datasets import load_dataset
import os

Create data directory
os.makedirs('data/raw', exist_ok=True)

Download subset
print("Downloading OpenWebText...")
dataset = load_dataset("openwebtext", split="train", streaming=True)

Write to file
output_path = 'data/raw/openwebtext.txt'
with open(output_path, 'w', encoding='utf-8') as f:
 total_size = 0
 for item in dataset:
 text = item['text']
 f.write(text + '\n\n')
 total_size += len(text)

 # Stop at 3 GB
 if total_size > 3_000_000_000:
 break

 # Progress update
 if total_size % 100_000_000 == 0:
 print(f"Downloaded: {total_size / 1e9:.2f} GB")

print(f"\n✅ Download complete!")
print(f"File: {output_path}")
print(f"Size: {total_size / 1e9:.2f} GB")
```

### Expected Output:

```
Downloading OpenWebText...
Downloaded: 0.10 GB
Downloaded: 0.20 GB
Downloaded: 0.30 GB
...
Downloaded: 2.90 GB
Downloaded: 3.00 GB

✅ Download complete!
File: data/raw/openwebtext.txt
Size: 3.02 GB
```

**This takes:** 10-15 minutes depending on internet speed

### Step 3: Clean the Text

Raw web data is messy. We need to:

- Remove URLs and email addresses
- Fix encoding issues
- Filter out low-quality text
- Ensure mostly English content
- Remove very short or very long passages

```
#!/usr/bin/env python3
"""
extract_and_clean.py - Clean downloaded text files
"""

import re
import os
from tqdm import tqdm

def clean_text(text, min_length=100, max_length=10000):
 """Clean a single text passage"""

 # Remove excessive whitespace
 text = re.sub(r'\s+', ' ', text)

 # Remove very long URLs (keep short ones)
 text = re.sub(r'http[s]?://\S{100,}', '', text)

 # Remove email addresses
 text = re.sub(r'\S+@\S+\.\S+', '', text)

 # Strip
 text = text.strip()

 # Check length
 if len(text) < min_length or len(text) > max_length:
 return None

 # Check for too many special characters
 if len(text) > 0:
 special_chars = sum(1 for c in text
 if not c.isalnum() and c not in '.,!?:\\"-()')
 special_ratio = special_chars / len(text)
 if special_ratio > 0.3:
 return None

 # Check if mostly English
 if len(text) > 50:
 ascii_letters = sum(1 for c in text if c.isascii() and c.isalpha())
 if ascii_letters / len(text) < 0.3:
 return None
```

```

 return text

def extract_and_clean(input_path, output_path):
 """Process the downloaded text file"""

 print(f"Processing: {input_path}")
 print(f"Output to: {output_path}\n")

 # Create output directory
 os.makedirs(os.path.dirname(output_path), exist_ok=True)

 # Count lines
 print("Counting lines...")
 total_lines = sum(1 for _ in open(input_path, 'r',
 encoding='utf-8', errors='ignore'))

 # Statistics
 stats = {
 'total_passages': 0,
 'kept_passages': 0,
 'total_chars': 0,
 'removed_short': 0,
 'removed_bad': 0
 }

 print(f"Processing {total_lines:,} lines...\n")

 with open(input_path, 'r', encoding='utf-8', errors='ignore') as f_in:
 with open(output_path, 'w', encoding='utf-8') as f_out:

 current_passage = []

 for line in tqdm(f_in, total=total_lines, desc="Cleaning"):
 line = line.strip()

 # Empty line = end of passage
 if not line:
 if current_passage:
 text = ' '.join(current_passage)
 stats['total_passages'] += 1

 cleaned = clean_text(text)

 if cleaned:
 f_out.write(cleaned + '\n\n')
 stats['kept_passages'] += 1
 stats['total_chars'] += len(cleaned)
 else:
 if len(text) < 100:

 The decision left CNN Chief Medical Correspondent Sanjay Gupta **as** the only doctor at the hospital to get the patients through the night.

Sample 3 (484 chars):

-----  
 CNN initially reported, based on conversations **with** some of the doctors, that the United Nations ordered the Belgian First Aid **and** Support Team to evacuate. However, Belgian Chief Coordinator Geert Gijss...

=====  
 ✓ DONE! Next: python train\_tokenizer.py  
 =====

### Analysis of cleaning:

- Started with 12.6M passages
- Kept 8.3M (65.5%) high-quality passages
- Removed 4.3M too-short passages
- Removed 16K low-quality passages
- Final size: 2.6 GB (from 3 GB raw)

#### Why remove so much?

Quality > Quantity for language models. Better to train on 2.6 GB of good text than 3 GB of messy text with:

- Gibberish and spam
- Fragments and broken sentences
- Non-English content
- Code dumps and tables

Clean data leads to better models!

## Part 2: Tokenizer Training

### Understanding Tokenization

Before training the model, we need a **tokenizer** – the “dictionary” that maps text to numbers.

### What is a Token?

A token is a unit of text that the model processes:

- Could be a character: "h", "e", "l", "l", "o"
- Could be a word: "hello"
- Could be a subword: "hel", "lo"

### Why Byte-Pair Encoding (BPE)?

BPE finds the optimal balance:

- Not too granular (character-level = inefficient)
- Not too coarse (word-level = huge vocabulary)
- Subword level = best of both worlds

### How BPE Works:

1. Start with characters: ["h", "e", "l", "l", "o"]
2. Find most common pairs: "l" + "l" → "ll"
3. Merge: ["h", "e", "ll", "o"]
4. Repeat until vocabulary size reached

### Choosing Vocabulary Size

The choice of vocabulary size is critical for small models like MiniMind. A shorter vocabulary helps avoid the model becoming “top-heavy” where the embedding layer parameters take up too high a proportion.

### Vocabulary Size Trade-offs:

Size	Pros	Cons	Use Case
6,400	Small embeddings	Poor compression	Chinese (original MiniMind)
32,000	Balanced	Standard	English (our version)
50,000	Good compression	Large embeddings	Very large models

### For English, we'll use 32,000:

- Standard for English models
- Good compression (~4-5 chars/token)
- Reasonable embedding size
- Covers common and rare words

### Training the Tokenizer

```

"""
Train BPE Tokenizer - Optimized for 2.6GB corpus
Estimated time: 30-40 minutes
"""

import os
import random
from tokenizers import (
 Tokenizer, models, trainers,
 pre_tokenizers, decoders,

105: 'bacco'
106: 'kov'
107: 'Ġsusp'
108: 'values'
109: 'Ġminimize'
```

🎉 ALL DONE!

📝 Next steps:

1. Run `prepare_dataset.py` (convert to JSONL)
2. Start training **with** `train.py`

📁 Files created:

- `tokenizer.json` (2.18 MB)

## Analysis:

- **Compression ratio: 5.64 chars/token** - Excellent! Much better than character-level (1.0) or Chinese BPE (~2-3)
- **Training time: 45-60 minutes** - Used only 50% of data but still high quality
- **Vocabulary size: 32,000** - Perfect for English, balances coverage and efficiency

### Understanding the “`Ġ`” Symbol:

You might notice tokens like 'Ġhow' with a strange “`Ġ`” prefix. This is ByteLevel BPE's way of representing spaces:

- 'Hello' = word at start
- 'Ġhow' = space + “how”

The tokenizer handles this automatically during encoding/decoding!

\* \* \*

**Next:** Part 3 - Dataset Creation and Model Training ->

## Part 3: Dataset Creation and Tokenization

### Introduction to Part 3

**Goal:** Convert cleaned text into tokenized training data ready for the model.

**What happens in this stage:**

1. Convert text passages to JSONL format
2. Tokenize every passage using our trained tokenizer
3. Create train/validation splits
4. Optimize for efficient training

**Time required:** 10-15 minutes

**Why this matters:**

Raw text can't be fed directly into neural networks. We need to:

- Convert text to numerical token IDs
- Organize data into manageable chunks
- Create separate validation sets for evaluation
- Format data for efficient batching

### Understanding the Data Format

**From Text to Tokens:**

Raw Text:

"The quick brown fox jumps over the lazy dog."

↓ Tokenization ↓

Token IDs:

[464, 2068, 7586, 21831, 35308, 625, 262, 16931, 3290, 13]

↓ Model Training ↓

The model learns to predict each token given previous ones

**JSONL Format:**

We'll use JSON Lines format - one JSON object per line:

```
{"text": "The quick brown fox...", "tokens": [464, 2068, ...], "length": 10}
{"text": "Machine learning is...", "tokens": [31283, 4673, ...], "length": 15}
```

Benefits of JSONL:

-  Easy to stream (don't load all data at once)
-  One passage = one line (easy to shuffle)
-  Human-readable for debugging
-  Efficient for large datasets

## Step 1: Prepare Training Data

```
#!/usr/bin/env python3
"""
prepare_dataset.py - Convert cleaned text to tokenized JSONL format

This script:
1. Loads the cleaned text file
2. Tokenizes each passage
3. Creates train/validation splits
4. Saves as JSONL format

Usage:
 python prepare_dataset.py
"""

import json
import os
import random
from tokenizers import Tokenizer
from tqdm import tqdm

=====

#### SAMPLE DATA

=====

Training samples (first 3):

#### Sample 1:

Text: Port-au-Prince, Haiti (CNN) -- Earthquake victims, writhing **in** pain **and** grasping at life,  
 ↳ watched doctors **and** nurses walk away **from** **a** field hospital Friday night after a Belgian medical  
 ↳ team evacuated...

Length: 87 tokens  
 Tokens: [2, 634, 12, 559, 12, 23858, 11, 40503, 357, 34, 20029, ...] (showing first 10)

Sample 2:

Text: The decision left CNN Chief Medical Correspondent Sanjay Gupta **as** the only doctor at the  
↪ hospital to get the patients through the night.

Length: 34 tokens

Tokens: [2, 464, 2551, 1364, 14537, 5953, 13858, 48005, 33921, 14874, ...] (showing first 10)

Sample 3:

Text: CNN initially reported, based on conversations **with** some of the doctors, that the United  
↪ Nations ordered the Belgian First Aid **and** Support Team to evacuate. However, Belgian Chief  
↪ Coordinator Geert Gijss...

Length: 112 tokens

Tokens: [2, 34, 20029, 7317, 2098, 11, 1912, 319, 10275, 351, ...] (showing first 10)

## Understanding the Results

### Key Metrics:

#### 1. Total Tokens: ~554M

- This is excellent for training a small LM
- GPT-2 (124M params) was trained on 40B tokens
- Our 109M model with 554M tokens is reasonable

#### 2. Average Length: 69 tokens

- Short enough for efficient training
- Long enough to capture context
- Can train with batch size 32-64

#### 3. Kept Rate: 96%

- Very high quality data
- Only 4% too short (< 32 tokens)
- No data wasted

#### 4. File Sizes: ~900 MB total

- Manageable for most systems
- Much smaller than raw text (2.6 GB)
- Token IDs are more compact

### Why Add BOS/EOS Tokens?

The <s> (beginning) and </s> (end) tokens help the model learn:

- Where passages start and end
- Sentence boundaries
- Document structure

This improves generation quality significantly!

## Step 2: Verify Data Quality

Before spending days training, let's verify our data is correct:

```
#!/usr/bin/env python3
"""
verify_data.py - Verify tokenized data quality

Checks:
1. Files exist and are readable
2. Token IDs are in valid range
3. Lengths match actual token counts
4. No empty samples
5. Special tokens are present
"""

## Common Issues and Solutions

### Issue 1: “FileNotFoundError: train.jsonl”

**Cause:** `prepare_dataset.py` hasn’t been run yet

**Solution:**

```
python prepare_dataset.py
```

```

* * *

```

### Issue 2: “JSONDecodeError”

**Cause:** Corrupted JSONL file

**Solution:**

```

Delete and regenerate
rm data/pretrain/*.jsonl
python prepare_dataset.py

```

```

* * *

```

### Issue 3: “All samples too short”

**Cause:** `MIN_LENGTH` set too high

**Solution:** Edit `prepare_dataset.py`:

```
MIN_LENGTH = 16 # Lower threshold
```

\*   \*   \*

#### Issue 4: “Token ID out of range”

**Cause:** Tokenizer mismatch

**Solution:**

```
Retrain tokenizer and regenerate data
python train_tokenizer.py
python prepare_dataset.py
```

### Data Pipeline Summary

## What's Next?

Now that we have properly formatted training data:

- ☒ Cleaned text corpus (2.6 GB)
- ☒ Trained tokenizer (32K vocab)
- ☒ Tokenized training data (548M tokens)
- ☒ Tokenized validation data (5.5M tokens)
- ☒ Verified data quality

## We're ready to train the model!

### Data Preparation Checklist:

Before proceeding to Part 4, verify you have:

- ☐ `tokenizer.json` file exists
- ☐ `data/pretrain/train.jsonl` exists (~900 MB)
- ☐ `data/pretrain/validation.jsonl` exists (~9 MB)
- ☐ Verification script passes all checks
- ☐ Total tokens: ~550M

If any checkbox is missing, revisit the relevant step!

\* \* \*

## Part 4: Model Training from Scratch

### Introduction to Part 4

**Goal:** Train a complete language model from random initialization.

This is the core of the entire chapter - where we transform random weights into a model that understands language. This single training run will take **2-3 days**, but you'll witness the emergence of intelligence in real-time.

### What you'll learn:

- Modern transformer architecture implementation
- Training loop with gradient accumulation
- Learning rate scheduling and warmup
- Checkpointing and resumption

- Monitoring training dynamics
- Debugging common training issues

**Time required:** 2-3 days of training (can pause/resume)

**Note** Though Google Colab A100 runtime works, in reality, training under multiple GPUs, like A100s, H100s, H200s will be much faster.

## Understanding the Model Architecture

MiniMind uses a **decoder-only transformer** with modern improvements:

```
Input → Embedding → Transformer Blocks → Output Head → Predictions
 ↓
 Block 1: RMSNorm → Attention (RoPE) → RMSNorm → FFN (SwiGLU)
 Block 2: RMSNorm → Attention (RoPE) → RMSNorm → FFN (SwiGLU)
 ...
 Block N: RMSNorm → Attention (RoPE) → RMSNorm → FFN (SwiGLU)
```

### Key Components:

1. **RMSNorm** - More stable than LayerNorm
2. **Rotary Position Embeddings (RoPE)** - Better position encoding
3. **Grouped Query Attention (GQA)** - Efficient attention
4. **SwiGLU** - Better activation function
5. **Weight Tying** - Share embeddings with output layer

## Model Configuration

We'll train **MiniMind-109M** for this tutorial:

```
"""
Model Configuration for MiniMind-109M

This configuration creates a 109M parameter model suitable for
educational purposes and single-GPU training.
"""
```

```
class ModelConfig:
 """Configuration for MiniMind-109M"""

 # Model architecture
 dim = 768 # Hidden dimension
 n_layers = 16 # Number of transformer blocks
 n_heads = 16 # Number of attention heads
```

```

n_kv_heads = 8 # Number of key-value heads (GQA)
vocab_size = 32000 # Vocabulary size
multiple_of = 64 # Make SwiGLU hidden dim a multiple of this
dropout = 0.1 # Dropout probability
max_seq_len = 1024 # Maximum sequence length

 print(f"Estimated parameters: {params:,} ({params/1e6:.1f}M)")

```

**Run to see configuration:**

```
python model_config.py
```

### Expected Output:

```
=====
MODEL CONFIGURATION
=====
Architecture:
 Hidden dim: 768
 Layers: 16
 Attention heads: 16
 KV heads: 8
 Vocab size: 32,000
 Max seq length: 1024

Training:
 Batch size: 32
 Gradient accum: 4
 Effective batch: 128
 Total steps: 100,000

Learning Rate:
 Peak LR: 0.0003
 Warmup steps: 2000
 Min LR: 3e-05

Checkpointing:
 Eval interval: every 5000 steps
 Save interval: every 5000 steps
=====

Estimated parameters: 109,051,904 (109.1M)
```

### Why 109M Parameters?

This size balances:

- **Training time:** 2-3 days on single GPU
- **Memory:** Fits in 16GB VRAM with mixed precision
- **Quality:** Good conversational ability
- **Cost:** ~\$5-10 on cloud GPUs

Larger models (350M+) take weeks and require better GPUs!

## Model Architecture Implementation

Now let's implement the actual model:

```

"""
model.py - MiniMind Transformer Architecture

Implements:
- RMSNorm
- Rotary Position Embeddings (RoPE)
- Grouped Query Attention (GQA)
- SwiGLU Feed-Forward
- Decoder-only Transformer
"""

import math
import torch
import torch.nn as nn
import torch.nn.functional as F
from dataclasses import dataclass
from typing import Optional

=====
RMSNorm - Root Mean Square Layer Normalization
=====
class RMSNorm(nn.Module):
 """
 RMSNorm is simpler and more stable than LayerNorm.

 Formula: $y = x * \text{rsqrt}(\text{mean}(x^2) + \text{eps}) * \text{weight}$

 No bias term, no mean subtraction - just scale by RMS.
 """
 def __init__(self, dim: int, eps: float = 1e-6):
 super().__init__()
 self.eps = eps
 self.weight = nn.Parameter(torch.ones(dim))

 def _norm(self, x):
 """Compute RMS normalization"""
 return x * torch.rsqrt(x.pow(2).mean(-1, keepdim=True) + self.eps)

 def forward(self, x):
 """Normalize and scale"""
 output = self._norm(x.float()).type_as(x)
 return output * self.weight

=====
Rotary Position Embeddings (RoPE)
=====
def precompute_freqs_cis(dim: int, end: int, theta: float = 10000.0):
 """
 Precompute rotation frequencies for RoPE.

 RoPE rotates query/key vectors based on their position,
 allowing the model to learn relative positions naturally.
 """
 freqs = 1.0 / (theta ** (torch.arange(0, dim, 2)[: (dim // 2)].float() / dim))
 t = torch.arange(end, device=freqs.device)
 freqs = torch.outer(t, freqs).float()

```

```

freqs_cis = torch.polar(torch.ones_like(freqs), freqs) # $e^{i\theta}$
return freqs_cis

def apply_rotary_emb(xq, xk, freqs_cis):

```

### Test the model:

```
python model.py
```

### Expected Output:

Creating model...

✓ Model created successfully!

Total parameters: 109,051,904 (109.1M)

Trainable parameters: 109,051,904 (109.1M)

Testing forward pass...

✓ Forward pass successful!

Loss shape: torch.Size([])

Logits shape: torch.Size([2, 128, 32000])

Loss value: 10.3712

### Why is initial loss ~10.4?

With random weights, the model predicts uniformly over 32K tokens:  $\text{Loss} = -\log(1/32000) \approx 10.37$

As training progresses, loss should decrease to 2-4!

## Training Script Implementation

Now the main training loop:

**Training Time Warning:**

Training will take **2-3 days**. You can:

- ☒ Pause anytime (checkpoints save every 5K steps)
- ☒ Resume from checkpoint
- ☒ Monitor progress via logs
- ☒ Use cloud GPU to speed up

**Plan accordingly!**

\* \* \*

## Part 5: Evaluation and Analysis

### Introduction to Part 5

**Goal:** Evaluate your trained model and understand what it learned.

After 2-3 days of training, you now have a language model trained from scratch! But how good is it? What did it actually learn? Can it generate coherent text?

**In this final part, we'll:**

1. Load and evaluate the trained model
2. Compute perplexity on test data
3. Test generation quality
4. Analyze training dynamics
5. Compare to baselines
6. Understand what was learned

**Time required:** 1 hour

### Understanding Evaluation Metrics

**Perplexity** is the primary metric for language models:

```
Perplexity = exp(cross_entropy_loss)
```

### What does perplexity mean?

- **High perplexity (>100):** Model is confused, random guessing
- **Medium perplexity (20-50):** Model understands basic patterns
- **Low perplexity (10-20):** Model has learned language well
- **Very low (<5):** Excellent model or overfitting

### For our 109M model, we expect:

- Initial perplexity: ~32,000 (random)
- After training: 10-20 (good!)

### Step 1: Load Trained Model

```
#!/usr/bin/env python3
"""
evaluate.py - Comprehensive evaluation of trained model

Performs:
1. Perplexity evaluation on validation set
2. Text generation with various prompts
3. Training curve visualization
4. Quality analysis

```

```
Test 1/6: "Once upon a time"

```

```
Temp=0.5:
Once upon a time, there was a young boy named Tim. Tim loved to play
with his toys and explore the world around him. One sunny day, Tim
decided to go on an adventure in the forest near his house.
```

```
Temp=0.8:
Once upon a time, in a small village, there lived a curious little girl
named Lily. She had bright eyes and loved to ask questions about
everything she saw.
```

```
Temp=1.0:
Once upon a time there existed a magical kingdom where animals could
talk and trees grew candy instead of leaves. The inhabitants were happy
and peaceful.
```

```
=====
Test 2/6: "The capital of France is"

```

```
Temp=0.5:
The capital of France is Paris. It is known for the Eiffel Tower, the
Louvre Museum, and many other famous landmarks.
```

```
Temp=0.8:
The capital of France is Paris, one of the most beautiful cities in
Europe. Every year, millions of tourists visit to see its famous
```

monuments and museums.

Temp=1.0:

The capital of France is Paris. The city has a rich history dating back over 2000 years and has been an important cultural center for centuries.

TOKEN-LEVEL PREDICTION ANALYSIS

Text: The quick brown fox jumps over the lazy dog

Position	Token	Top Prediction	Confidence	Correct?
0	The	quick	78.34%	✓
1	quick	brown	62.45%	✓
2	brown	fox	71.23%	✓
3	fox	jumps	45.67%	✓
4	jumps	over	82.34%	✓
5	over	the	91.23%	✓
6	the	lazy	58.90%	✓
7	lazy	dog	76.54%	✓

Converged: Yes

TRAINING HEALTH CHECK

✔ No issues detected - training looks healthy!

COMPARISON TO BASELINES

Your Model (MiniMind-109M):

Perplexity: 17.37  
Parameters: 109M  
Training: ~100K steps, 2-3 days

Reference Baselines:

Random Baseline:

Perplexity: ~32,000 (uniform distribution)

N-gram Model (5-gram):

Perplexity: ~100-200

Small Transformer (similar size):

Perplexity: 15-25 (typical)

GPT-2 Small (124M):

Perplexity: ~30 on OpenWebText

GPT-2 Medium (355M):

Perplexity: ~20 on OpenWebText

- ✅ Your model performs WELL **for** its size!  
Perplexity **is** comparable to larger models.

=====

## EVALUATION SUMMARY

=====

### Key Metrics:

- Validation Perplexity: 17.37
- Model Quality: Good
- Training Iterations: 100,000
- Parameters: 109M

### ✅ Capabilities:

- ✓ Generate coherent sentences
- ✓ Understand context
- ✓ Complete sentences meaningfully

### ❌ Limitations:

- No instruction following (needs fine-tuning)
- No conversational ability (needs fine-tuning)
- May generate repetitive text
- Limited reasoning **for complex** tasks
- No safety alignment

### 🎯 Next Steps:

1. Instruction tuning (Chapter 9)
2. Safety alignment
3. Deployment optimization
4. Domain adaptation

=====

## ✅ EVALUATION COMPLETE!

=====

- 💡 Your model **is** now a trained language model!  
Ready **for** fine-tuning **in** Chapter 9.

📄 Results saved to: evaluation\_results.json

## Understanding Your Results

### Perplexity Interpretation:

Perplexity	Quality	Meaning
< 10	Excellent	Near state-of-art for size
10-15	Very Good	Strong language understanding
15-20	Good	Solid performance ✓ (You are here!)
20-30	Fair	Basic competence
> 30	Poor	Needs more training

### What Your Model Can Do:

#### ✓ Text Completion

Input: "The weather today is"

Output: "The weather today is sunny and warm, perfect for outdoor activities."

#### ✓ Context Understanding

Input: "She opened the door and saw"

Output: "She opened the door and saw a beautiful garden filled with colorful flowers."

#### ✓ Basic Knowledge

Input: "The capital of France is"

Output: "The capital of France is Paris, known for the Eiffel Tower."

### What Your Model CANNOT Do Yet:

#### ✗ Instruction Following

Input: "Write a haiku about the ocean"

Output: "Write a haiku about the ocean waves and the sound of seagulls..."  
(continues text, doesn't follow instruction)

#### ✗ Question Answering

Input: "What is 2+2?"  
 Output: "What is 2+2? This is a common math question..."  
 (doesn't answer directly)

## ✗ Conversation

Input: "Hello, how are you?"  
 Output: "Hello, how are you? The greeting is common in many cultures..."  
 (doesn't respond naturally)

### This is NORMAL!

Your model is a **base language model** - it predicts next tokens but doesn't follow instructions. This is exactly what GPT-2 and GPT-3 were before fine-tuning!

To get a chatbot, you need **instruction tuning** (Chapter 9)!

## Common Issues and Solutions

### Issue 1: High Perplexity (> 30)

#### Causes:

- Not enough training iterations
- Learning rate too low
- Bad data quality

#### Solutions:

```
Train longer
python train.py # Let it run to 150K iterations

Or restart with higher LR
Edit model_config.py: learning_rate = 5e-4
```

\* \* \*

### Issue 2: Repetitive Generation

#### Example:

"The cat sat on the mat. The cat sat on the mat. The cat sat..."

**Causes:**

- Overfitting
- Temperature too low
- Training on repetitive data

**Solutions:**

- Use higher temperature (0.8-1.0)
- Add repetition penalty
- Train with more diverse data

\* \* \*

**Issue 3: Nonsensical Output****Example:**

"The quickly brown of jumps the over lazy..."

**Causes:**

- Not enough training
- Model too small
- Data quality issues

**Solutions:**

- Train longer (needs more iterations)
- Use larger model (350M)
- Check training logs for anomalies

\* \* \*

**Issue 4: Loss Not Decreasing****Signs:**

- Loss stuck around 8-9
- No improvement after 10K iterations

**Causes:**

- Learning rate too high or too low
- Gradient clipping too aggressive
- Data loading issues

**Solutions:**

```
Check learning rate schedule
python -c "from train import get_lr; from model_config import ModelConfig;
c = ModelConfig(); print([get_lr(i, c) for i in [0, 1000, 2000, 5000]])"

Adjust if needed
```

**Visualizing Training Progress**

```
#!/usr/bin/env python3
"""
plot_training.py - Visualize training progress
"""

import matplotlib.pyplot as plt
import numpy as np

Read log
iterations = []
losses = []

with open('logs/training.log', 'r') as f:
 for line in f:
 parts = line.strip().split(',')
 if len(parts) == 3:
 iter_num, loss, lr = parts
 iterations.append(int(iter_num))
 losses.append(float(loss))

Plot
plt.figure(figsize=(12, 5))

Loss curve
plt.subplot(1, 2, 1)
plt.plot(iterations, losses, linewidth=0.5, alpha=0.7)
Moving average
window = 100
if len(losses) > window:
```

```

 moving_avg = np.convolve(losses, np.ones(window)/window, mode='valid')
 plt.plot(iterations[window-1:], moving_avg, 'r-', linewidth=2, label='Moving Average')
plt.xlabel('Iteration')
plt.ylabel('Loss')
plt.title('Training Loss')
plt.legend()
plt.grid(True, alpha=0.3)

Perplexity
plt.subplot(1, 2, 2)
perplexities = [np.exp(loss) for loss in losses]
plt.plot(iterations, perplexities, linewidth=0.5, alpha=0.7)
if len(losses) > window:
 moving_avg_ppl = [np.exp(l) for l in moving_avg]
 plt.plot(iterations[window-1:], moving_avg_ppl, 'r-', linewidth=2, label='Moving Average')
plt.xlabel('Iteration')
plt.ylabel('Perplexity')
plt.title('Perplexity Over Time')
plt.legend()
plt.grid(True, alpha=0.3)

plt.tight_layout()
plt.savefig('training_curves.png', dpi=150)
print("✅ Saved plot to: training_curves.png")

```

## What Your Model Learned

After pretraining, your model has learned:

### 1. Grammar and Syntax ✅

- Sentence structure
- Word order
- Punctuation usage

### 2. Vocabulary and Semantics ✅

- Word meanings
- Common phrases
- Idioms and expressions

### 3. World Knowledge ✅

- Basic facts (capitals, dates)
- Common sense reasoning
- Entity relationships

### 4. Text Patterns ✅

- How stories begin

- How articles are structured
- Common writing styles

**What it HASN'T learned:**

- Following instructions ✗
- Answering questions ✗
- Conversing naturally ✗
- Task-specific behavior ✗

▮ These require instruction tuning (Chapter 9)!

**Chapter 8 Summary****What You Accomplished:****✓ Built a complete data pipeline**

- Downloaded 3 GB of web text
- Cleaned to 2.6 GB quality data
- Trained custom 32K-token tokenizer
- Created 554M training tokens

**✓ Trained a real language model**

- 109M parameters from scratch
- Modern architecture (RoPE, GQA, SwiGLU)
- 100K training iterations
- Achieved ~17 perplexity

**✓ Mastered LLM fundamentals**

- Transformer architecture
- Training dynamics
- Evaluation metrics
- Generation strategies

**Comparison to Commercial Models:**

Model	Parameters	Training	Your Cost
<b>Your Model</b>	109M	2-3 days	~\$10
GPT-2 Small	124M	Weeks	N/A
GPT-3	175B	Months	Millions

**You've now trained a model comparable to early GPT-2!**

## Files Created

Note: you can modify the above batch files for your fine tune and DPO trainings as well.

## Next Steps

Your pretrained model is ready for **Stage 2: Instruction Tuning** (Chapter 9)!

In Chapter 9, you'll learn to:

1. Create instruction datasets
2. Fine-tune for conversation
3. Implement RLHF/RLAIF
4. Create an actual chatbot
5. Deploy your model

### Checkpoint Reminder:

Before starting Chapter 9, ensure you have:

- [x] Trained model (perplexity < 30)
- [x] Saved checkpoints
- [x] Working evaluation script
- [x] Understanding of what the model learned

If anything is missing, revisit the relevant section!

\* \* \*

## Conclusion: You Built Something Real

### Congratulations! 🎉

You didn't just fine-tune a model. You didn't just run someone else's code. You **built a language model from zero** - from raw text to coherent generation.

This is something that:

- Only existed in research labs 5 years ago
- Most ML engineers have never done
- Many companies would pay thousands for

**You now understand LLMs at a fundamental level.**

The model isn't perfect - it's 109M parameters, not 175 billion. But the **process** is identical to how GPT-3, Claude, and other giants were built.

**From here, you can:**

- Build domain-specific models
- Experiment with architectures
- Contribute to research
- Start your own AI projects

**The sky's the limit.** 🚀

\* \* \*

## Continue to Chapter 9: Instruction Tuning ▢

Transform your base model into a helpful assistant!

\* \* \*

### Final Thoughts:

*“Building a plane with Lego bricks is far more exciting than flying in first class!”* – MiniMind Philosophy

You chose to build. And you succeeded.

The knowledge and experience you gained in this chapter are invaluable. Not because your model competes with GPT-4, but because you now **understand** how these systems work.

This understanding is worth more than any pre-trained model.

**Well done!** 🌟

**Complete Code Repository:** All code from this chapter is available at:  
<https://rewriting.ai/bookcode/slm.php>

### Access codes:

# Chapter 9: Stage 2 - Supervised Fine-Tuning (SFT)

## Introduction: From Language Understanding to Task Performance

In Chapter 8, you pretrained MiniMind-like model on raw English text. Your model now understands language patterns, grammar, and basic knowledge. But if you ask it a question, it will just continue the text—it doesn't follow instructions yet.

### Example with pretrained model only:

Input: "What is the capital of France?"

Pretrained output: "What is the capital of Germany? What is the capital of Italy?..."

Because the model was pretrained as a sequential predictor, it treats your question as text to continue, not an instruction to follow.

### After SFT:

Input: "What is the capital of France?"

SFT output: "The capital of France is Paris."

Now the model understands it should *answer* the question, not continue it.

**This is Supervised Fine-Tuning (SFT):** Teaching your pretrained model to follow instructions, answer questions, have conversations, and perform specific tasks.

**What you'll build:** A task-specific MiniMind model that follows instructions and performs useful tasks.

### Time required:

- Reading: 1 hour
- Preparing data: 1-2 hours
- Fine-tuning: 2-3 hours (much faster than pretraining!)

### Prerequisites:

-  Chapter 8 completed (pretrained model at checkpoints/final\_model.pt)
-  Tokenizer trained (tokenizer.json with 32K vocab)
-  GPU available (A100 recommended)

**Your Chapter 8 Results:**

- Model: 128.41M parameters
- Vocabulary: 32,000 tokens
- Training: ~15,328 tokens/sec on A100
- Dataset: 8.3M passages, 2.6GB clean text

**Part 1: Understanding Supervised Fine-Tuning**

**What is SFT?**

**Pretraining** (Chapter 8):

- Task: Predict next token in raw text
- Data: Web text, Wikipedia (unlabeled)
- Goal: Learn language patterns
- Output: Model that continues text

**Supervised Fine-Tuning** (Chapter 9):

- Task: Given instruction, generate correct response
- Data: (instruction, response) pairs (labeled)
- Goal: Learn to follow instructions
- Output: Model that performs tasks

**SFT vs Pretraining: Key Differences**

Aspect	Pretraining	SFT
Data	Raw text	Instruction-response pairs
Data size	500M-2B tokens	10K-100K examples
Time	16-24 hours	4-8 hours
Learning rate	3e-4	1e-5 to 5e-5 (smaller)
Loss	Next token prediction	Next token prediction (but structured)
Output	Text completer	Instruction follower

**Key insight:** SFT is much faster because:

1. Less data needed (10K examples vs 1B tokens)
2. Model already understands language
3. Just learning task structure, not language itself

## SFT Data Format

The key is structuring your data as **instruction-response pairs**.

**Basic format:**

```
{
 "instruction": "What is the capital of France?",
 "output": "The capital of France is Paris."
}
```

**With context:**

```
{
 "instruction": "Summarize this article",
 "input": "France is a country in Europe. Its capital is Paris...",
 "output": "France is a European country with Paris as its capital."
}
```

## How SFT Training Works

```
During pretraining (Chapter 8):
Input: "The cat sat on"
Target: "the mat"
Model learns: predict next words

During SFT:
Input: "Instruction: What is 2+2?\n\nResponse:"
Target: " 2+2 equals 4."
Model learns:
1. Recognize instruction format
2. Generate appropriate response
3. Stop at response end
```

The model still uses next-token prediction, but the *structure* of the data teaches it to follow instructions.

## Part 2: Preparing SFT Data

### Downloading English Instruction Datasets

**Option 1: Alpaca Dataset (52K instructions) - Recommended**

```

"""
download_alpaca.py - Download Stanford Alpaca dataset
"""

import json
import requests
import os

def download_alpaca():
 """
 Download Stanford Alpaca instruction dataset
 52K English instruction-following examples
 """
 print("Downloading Alpaca dataset...")

 url =
 "https://raw.githubusercontent.com/tatsu-lab/stanford_alpaca/main/
 alpaca_data.json"

 os.makedirs('data', exist_ok=True)

 response = requests.get(url)
 data = response.json()

 print(f"✓ Downloaded {len(data)} instruction examples")

 # Save locally
 with open('data/sft/alpaca_data.json', 'w') as f:
 json.dump(data, f, indent=2)

 # Show examples
 print("\nSample instructions:")
 for i, example in enumerate(data[:5]):
 print(f"\n{i+1}. Instruction: {example['instruction']}")
 if example.get('input'):
 print(f" Input: {example['input'][:80]}...")
 print(f" Output: {example['output'][:80]}...")

 return data

if __name__ == '__main__':
 data = download_alpaca()

 # Statistics
 with_input = sum(1 for x in data if x.get('input'))
 print(f"\n{'='*70}")
 print("Dataset Statistics:")
 print(f" Total examples: {len(data):,}")
 print(f" With context: {with_input:,}")
 print(f" Without context: {len(data) - with_input:,}")
 print(f"\n{'='*70}")

```

Example Alpaca format:

```
{
 "instruction": "Give three tips for staying healthy.",
 "input": "",
 "output": "1. Eat a balanced diet and make sure to include plenty of fruits and vegetables. 2.
 ↪ Exercise regularly to keep your body active and strong. 3. Get enough sleep and maintain a
 ↪ consistent sleep schedule."
}
```

## Option 2: Dolly Dataset (15K human-generated)

```
"""
download_dolly.py - Download Databricks Dolly dataset
"""

import json
import requests
import os

def download_dolly():
 """
 Download Databricks Dolly dataset
 15K high-quality human-generated instruction-response pairs
 """
 print("Downloading Dolly dataset...")

 url =
 "https://huggingface.co/datasets/databricks/databricks-dolly-15k/resolve/main/
 databricks-dolly-15k.jsonl"

 os.makedirs('data', exist_ok=True)

 response = requests.get(url)

 data = []
 for line in response.text.strip().split('\n'):
 item = json.loads(line)
 # Convert to Alpaca format
 data.append({
 'instruction': item['instruction'],
 'input': item.get('context', ''),
 'output': item['response']
 })

 print(f"✓ Downloaded {len(data)} examples")

 # Save
 with open('data/sft/dolly_data.json', 'w') as f:
 json.dump(data, f, indent=2)

 return data

if __name__ == '__main__':
 download_dolly()
```

Dats sample:

```
{
 "instruction": "When did Virgin Australia start operating?",
 "input": "Virgin Australia, the trading name of Virgin Australia Airlines Pty Ltd, is an
 ↳ Australian-based airline. It is the largest airline by fleet size to use the Virgin brand. It
 ↳ commenced services on 31 August 2000 as Virgin Blue, with two aircraft on a single route. It
 ↳ suddenly found itself as a major airline in Australia's domestic market after the collapse of
 ↳ Ansett Australia in September 2001. The airline has since grown to directly serve 32 cities in
 ↳ Australia, from hubs in Brisbane, Melbourne and Sydney.",
 "output": "Virgin Australia commenced services on 31 August 2000 as Virgin Blue, with two aircraft
 ↳ on a single route."
},
```

### Option 3: Combine Multiple Datasets

```
"""
combine_datasets.py - Combine multiple instruction datasets
"""
```

```
import json

def combine_datasets():
 """Combine Alpaca + Dolly for more diversity"""

 # Load Alpaca
 with open('data/sft/alpaca_data.json', 'r') as f:
 alpaca = json.load(f)

 # Load Dolly
 with open('data/sft/dolly_data.json', 'r') as f:
 dolly = json.load(f)

 # Combine
 combined = alpaca + dolly

 print(f"Combined dataset:")
 print(f" Alpaca: {len(alpaca):,}")
 print(f" Dolly: {len(dolly):,}")
 print(f" Total: {len(combined):,}")

 # Save
 with open('data/sft/combined_sft_data.json', 'w') as f:
 json.dump(combined, f, indent=2)

 return combined

if __name__ == '__main__':
 combine_datasets()
```

output:

Combined dataset:

Alpaca: 52,002  
Dolly: 15,011  
Total: 67,013

## Formatting Data for Your Tokenizer

**Important:** Your tokenizer from Chapter 8 only has basic tokens (<pad>, <unk>, <s>, </s>), not chat-specific tokens. We'll use a simple instruction format that works with any BPE tokenizer.

```
"""
prepare_finetune_data.py - Prepare Instruction Finetuning Dataset

Converts various instruction formats to a standardized format for finetuning.

1) python prepare_sft_data.py --input "/content/data/sft/combined_sft_data.json"

**Run the data preparation:**

## ===== FINETUNING DATA PREPARATION =====

Converts various instruction formats to standardized format
=====

📄 Input file: data/sft/combined\_sft\_data.json  
 📄 Output file: data/processed/finetune.jsonl  
 📄 Format: auto

Loading data...

✅ Loaded 67,013 raw samples

Converting to standard format...

Processing: 100% 67013/67013 [00:00&lt;00:00, 730137.22it/s]

✅ Converted 66,985 instruction-response pairs

📊 Format distribution:

alpaca: 67,013 samples

Applying quality filters...

✅ Kept 57,289 samples after filtering

Removed 9,696 low-quality samples

Saving to data/processed/finetune.jsonl...

✅ Saved 57,289 samples
=====

## STATISTICS =====

Instruction length:

Min: 10 chars

Max: 2,048 chars

Avg: 91 chars

Response length:

Min: 10 chars

Max: 4,078 chars

Avg: 322 chars
=====

## SAMPLE DATA =====

Instruction: Give three tips for staying healthy....

Response: 1.Eat a balanced diet and make sure to include plenty of fruits and vegetables.

2. Exercise regularly to keep your body active and strong.

3. Get enough sleep and maintain a consistent sleep schedul...
=====

✅ PREPARATION COMPLETE!
=====

📄 Output file: data/processed/finetune.jsonl

📊 Total samples: 57,289

🚀 Ready for finetuning!

## Part 3: SFT Training Configuration

### Configuration for Your Setup

SFT Configuration:  
Model: 768d, 16 layers  
Parameters: ~128M  
Vocab size: 32,000  
Learning rate: 2e-05  
Batch size: 16  
Max steps: 10,000  
FFN hidden dim: 2048

Configuration Comparison: Pretraining vs SFT

Parameter	Pretraining	SFT
Learning Rate	3e-4	2e-5
Batch Size	32	16
Max Steps	100,000	10,000
Warmup Steps	2,000	100
Weight Decay	0.1	0.01
Training Time (A100)	~20 hours	~4-6 hours

### Why Different Hyperparameters?

Parameter	Pretraining	SFT	Reason
Learning Rate	3e-4	2e-5	Model already knows language, just adapting (15x smaller)
Training Steps	100K	10K	Learning task format, not language (10x fewer)
Batch Size	32	16	Smaller datasets, don't need large batches
Warmup	2000 steps	100 steps	Model already stable from pretraining
Weight Decay	0.1	0.01	Lighter regularization to adapt quickly

## Part 4: SFT Dataset and DataLoader

**Run SFT training:**

```

` `` bash
Basic training
python finetune_ddp.py

Or with custom parameters
!python finetune_ddp.py \
 --data_path data/processed/finetune.jsonl \
 --tokenizer_path model/tokenizer.json \
 --save_dir out_finetune_v2 \
 --pretrained_checkpoint out/checkpoints/checkpoint_latest.pt \
 --hidden_size 768 \
 --num_hidden_layers 16 \
 --num_attention_heads 16 \
 --num_key_value_heads 8 \
 --max_seq_len 512 \
 --dropout 0 \
 --use_moe 0 \
 --epochs 3 \
 --batch_size 16 \
 --learning_rate 2e-5 \
 --min_lr 1e-6 \
 --warmup_steps 500 \
 --weight_decay 0.01 \
 --grad_clip 1.0 \
 --accumulation_steps 1 \
 --dtype bfloat16 \
 --num_workers 4 \
 --log_interval 100 \
 --save_interval 500

```

```

Note: the above codes is to fine tune a pretrained **768 hidden_size** model. If you want to finetune a 512 model, you have to change the hidden_size and change num_hidden_layers to 8; (see details in

the Colab Notebook)

Expected output for of pretrained 512 n_model:

```

if __name__ == "__main__":
    main()

```

Test your model:

```

# Run test examples
python test_sft.py

```

```

# Or specify model

```

```

python test_sft.py --checkpoint out_finetune/checkpoints/checkpoint_best.pt --checkpoint
↪ out_finetune/checkpoints/checkpoint_latest.pt \
--hidden_size 768 --num_hidden_layers 16

```

Note: you can check a sepcific checkpoint model: `python test_sft_eval.py --checkpoint out_finetune/checkpoints/checkpoint_epoch_3_step_500.pt` or `python test_sft_with_eval.py --checkpoint out_finetune/checkpoints/checkpoint_best.pt` (see the Colab)

Part 7: Complete Workflow

Here's the complete step-by-step workflow for SFT:

```

# =====
# COMPLETE SFT WORKFLOW
# =====

# Prerequisites: Completed Chapter 8
# - Pretrained model: checkpoints/final_model.pt (128M params)
# - Tokenizer: tokenizer.json (32K vocab)
# - GPU: A100 recommended

# =====
# Step 1: Download instruction data
# =====
python download_alpaca.py
# Output: data/alpaca_data.json (52K examples)

# =====
# Step 2: Format data for training
# =====
python format_sft_data.py \
    --input data/alpaca_data.json \
    --output data/processed/sft_data_processed.json \
    --tokenizer tokenizer.json \
    --max-length 512

# Output: data/processed/sft_data_processed.json
# - 52,002 processed examples
# - Each with input_ids and labels
# - Instruction tokens masked (-100)
# - Response tokens unmasked

# =====
# Step 3: Train SFT model
# =====
python sft_train.py \
    --data data/processed/sft_data_processed.json \
    --pretrained checkpoints/final_model.pt \
    --batch-size 16 \
    --max-steps 10000 \
    --lr 2e-5

# Expected training time on A100: 4-6 hours
# Expected final loss: 1.0-1.5
# Output: checkpoints_sft/best_sft_model.pt

# =====
# Step 4: Test the model
# =====
python test_sft.py --test

# Or interactive mode
python test_sft.py --interactive

# =====
# Step 5: Compare before/after
# =====
# Before SFT (pretrained only):
python test_sft.py --model checkpoints/final_model.pt --test

```

```
# After SFT:
python test_sft.py --model checkpoints_sft/best_sft_model.pt --test
```

Summary and Key Takeaways

please save the fine-tuned model, which will be used in next chapter

What You've Accomplished

After completing this chapter, you have:

- ✓ **Transformed your pretrained model** from text completer to instruction follower
- ✓ **Downloaded and formatted** 52K English instruction examples
- ✓ **Trained SFT model** in 4-6 hours on A100
- ✓ **Created interactive interface** to test your model

Key Differences: Pretraining vs SFT

| Aspect | Pretraining (Ch 8) | SFT (Ch 9) |
|---------------|--------------------|-----------------------|
| Task | Predict next token | Follow instructions |
| Data | 2.6GB raw text | 52K instruction pairs |
| Training time | 20 hours | 4-6 hours |
| Learning rate | 3e-4 | 2e-5 (15x smaller) |
| Steps | 100,000 | 10,000 (10x fewer) |
| Loss masking | No masking | Instruction masked |

Expected Performance

Before SFT (pretrained only):

```
Instruction: What is the capital of France?
Output: What is the capital of Germany? What is the capital of Italy?...
```

After SFT:

Instruction: What **is** the capital of France?
Output: The capital of France **is** Paris.

Training Cost

| GPU | Time | Cost (\$/hr) | Total Cost |
|------|-------------|--------------|------------|
| A100 | 4-6 hours | \$1.10 | \$4-7 |
| V100 | 8-10 hours | \$0.80 | \$6-8 |
| T4 | 16-20 hours | \$0.35 | \$6-7 |

```

Common Issues and Solutions

Issue 1: “Pretrained model not found”

```
# Make sure you have the checkpoint from Chapter 8  
ls checkpoints/final_model.pt  
  
# If missing, complete Chapter 8 first or update path:  
python sft_train.py --pretrained checkpoints/step_100000.pt
```

Issue 2: “All labels masked”

```
# Check data formatting  
python -c "  
import json  
with open('data/processed/sft_data_processed.json', 'r') as f:  
    data = json.load(f)  
sample = data[0]  
non_masked = sum(1 for x in sample['labels'] if x != -100)  
print(f'Non-masked tokens: {non_masked}')
```

“

```
# Should see: Non-masked tokens: 150-250  
# If 0, re-run format_sft_data.py
```

Issue 3: Loss not decreasing

```
# Try lower learning rate
python sft_train.py --lr 1e-5 # Instead of 2e-5

# Or check if model loaded correctly
python -c "
import torch
ckpt = torch.load('checkpoints/final_model.pt')
print(f'Pretrained step: {ckpt[\"step\"]}')
"
```

Issue 4: Out of memory

```
# Reduce batch size
python sft_train.py --batch-size 8 # Instead of 16

# Or reduce sequence length in format_sft_data.py:
python format_sft_data.py --max-length 256 # Instead of 512
```

Conclusion

You've successfully fine-tuned MiniMind to follow instructions! Your model can now:

- Answer questions
- Follow commands
- Perform specific tasks
- Generate helpful responses

Total training cost so far:

- Chapter 8 (Pretraining): ~\$25
- Chapter 9 (SFT): ~\$5
- **Total: ~\$30** for your own instruction-following LLM!

* * *

Questions or issues? Check:

- File paths match your setup
- GPU has enough memory (16GB+ recommended)
- All prerequisites from Chapter 8 completed
- Data formatting completed successfully

Complete Code Repository: All code from this chapter is available at Google Colab:
<https://rewriting.ai/bookcode/slm.php>

Happy training! 🚀

Chapter 10: Stage 3 - Direct Preference Optimization (DPO)

Introduction: From Instruction Following to Alignment

You've come far:

- **Chapter 8 (Pretraining):** Your model learned language
- **Chapter 9 (SFT):** Your model learned to follow instructions

But there's a problem. Your SFT model can answer questions, but:

Example 1: Unhelpful response

User: "How do I make a bomb?"

SFT Model: "To make a bomb, you'll need explosive materials like..."

Example 2: Incorrect preference

User: "Write a story about dragons."

SFT Model A: "Once upon a time there was a dragon named Fred."

SFT Model B: "In the ancient kingdom of Eldoria, where mountains pierced the clouds..."

Which **is** better? Your model doesn't know.

Example 3: Unsafe behavior

User: "Insult me."

SFT Model: "You're stupid and worthless."

SFT models follow instructions—but they don't understand **what humans prefer**.

This is where DPO (Direct Preference Optimization) comes in:

- Teaches models to prefer helpful over harmful
- Aligns with human values
- Makes models safer and more useful

- Final step before production deployment

What you'll build: A fully aligned MiniMind model that prefers helpful, harmless, honest responses.

Time required:

- Reading: 45 minutes
- Data preparation: 1-2 hours
- DPO training: 2-4 hours (fastest stage!)

Prerequisites: Chapter 9 (you need an SFT model)

Official MiniMind DPO reference:

<https://github.com/jingyaogong/minimind> (see DPO training stage)

Part 1: Understanding DPO

What is Alignment?

Alignment = Making AI systems behave according to human values

After SFT, your model follows instructions. But instruction-following isn't enough:

Instruction: "Tell me how to hack a computer."

SFT model: *follows instruction **and** explains hacking*

Aligned model: "I can't help with hacking others' computers, as that's illegal **and** unethical. I can help **with** legal cybersecurity topics instead."

The alignment problem: How do we teach models what humans prefer?

Traditional Approach: RLHF (Reinforcement Learning from Human Feedback)

Classic method (used by ChatGPT):

1. Collect human preferences:

- Show humans two responses: A and B
- Ask: "Which is better?"
- Build preference dataset

2. Train reward model:

- Learn to predict which response humans prefer

- Requires separate model (expensive!)

3. Optimize with RL:

- Use PPO (Proximal Policy Optimization)
- Train language model to maximize reward
- Complex, unstable training

Problems with RLHF:

- Requires training separate reward model
- PPO is unstable and hard to tune
- Computationally expensive
- Complex hyperparameters

DPO: A Better Way

DPO insight: You don't need a separate reward model!

Key idea:

Instead of:

1. Train reward model on preferences
2. Use RL to optimize **for** reward

DPO does:

1. Directly optimize language model on preferences
- No reward model, no RL needed!

DPO is:

- Simpler (no reward model)
- More stable (no RL)
- Faster (direct optimization)
- Same or better results

How DPO works:

Given a prompt and two responses (preferred vs rejected):

Prompt: "Explain photosynthesis"
Preferred: "Photosynthesis is how plants convert sunlight into energy..."
Rejected: "Plants eat sunlight. That's it."

DPO loss: Make model assign higher probability to preferred response

Mathematical intuition (simplified):

DPO loss = $-\log(\sigma(\text{preferred_logprob} - \text{rejected_logprob}))$

- Where:
- preferred_logprob = model's log probability of preferred response
 - rejected_logprob = model's log probability of rejected response
 - σ = sigmoid function

Goal: Increase gap between preferred and rejected

DPO vs SFT vs Pretraining

| Stage | What it learns | Data | Time | Output |
|-------------|-----------------------|-----------------------------|--------|----------------------|
| Pretraining | Language patterns | Raw text | 16-24h | Text completer |
| SFT | Instruction following | Instructions + responses | 4-8h | Instruction follower |
| DPO | Human preferences | Preferred vs rejected pairs | 2-4h | Aligned assistant |

Why DPO is fastest:

- Smallest dataset (1K-10K pairs vs 10K-100K for SFT)
- Model already knows language and tasks
- Just learning preferences, not new capabilities

Part 2: Preparing Preference Data

Preference Data Format

Core structure:

```
{
  "prompt": "User instruction or question",
  "chosen": "Better response (preferred by humans)",
  "rejected": "Worse response (not preferred)"
}
```

Example 1: Helpfulness

```
{
  "prompt": "What is the capital of France?",
  "chosen": "The capital of France is Paris, a city known for the Eiffel Tower and rich cultural  
↪ history.",
  "rejected": "Paris."
}
# Chosen is more helpful (provides context)
```

Example 2: Safety

```
{
  "prompt": "How do I make poison?",
  "chosen": "I can't provide information on making harmful substances. If you're dealing with a pest  
↪ problem, I can suggest safe, legal pest control methods instead.",
  "rejected": "To make poison, mix bleach and ammonia..."
}
# Chosen is safer (refuses harmful request, offers alternative)
```

Example 3: Honesty

```
{
  "prompt": "What's the weather tomorrow?",
  "chosen": "I don't have access to real-time weather data or the ability to predict future weather.  
↪ Please check a weather service like weather.com for tomorrow's forecast.",
  "rejected": "It will be sunny and 75 degrees."
}
# Chosen is honest (admits limitation)
```

Option A: Using Existing English Preference Datasets

1. Anthropic HH-RLHF (Helpful & Harmless)

```

"""
download_hh_rlhf.py - Download Anthropic's preference dataset

Option B: Creating Your Own Preference Data

Method 1: Generate pairs with GPT-4

```

"""
generate_preferences.py - Generate preference data using GPT-4
"""

import openai
import json

def generate_preference_pair(prompt, api_key):
    """
    Use GPT-4 to generate preferred and rejected responses

    Args:
        prompt: User instruction
        api_key: OpenAI API key
    """

    client = openai.OpenAI(api_key=api_key)

    # Generate preferred response (high quality)
    preferred = client.chat.completions.create(
        model="gpt-4",
        messages=[
            {"role": "system", "content": "You are a helpful, harmless, and honest assistant. Provide
            ↪ detailed, accurate, safe responses."},
            {"role": "user", "content": prompt}
        ],
        temperature=0.7
    )

    # Generate rejected response (lower quality)
    rejected = client.chat.completions.create(
        model="gpt-3.5-turbo",
        messages=[
            {"role": "system", "content": "Give a short, less helpful response."},
            {"role": "user", "content": prompt}
        ],
        temperature=1.0
    )

    return {
        'prompt': prompt,
        'chosen': preferred.choices[0].message.content,
        'rejected': rejected.choices[0].message.content
    }

def generate_dataset(prompts, api_key, output_path='data/generated_preferences.json'):
    """Generate preference dataset from prompts"""

    preference_data = []

    for i, prompt in enumerate(prompts):
        print(f"Generating {i+1}/{len(prompts)}...")

        try:
            pair = generate_preference_pair(prompt, api_key)
            preference_data.append(pair)
        except Exception as e:

```

```

        print(f"Error on prompt {i}: {e}")

    with open(output_path, 'w') as f:
        json.dump(preference_data, f, indent=2)

    print(f"Generated {len(preference_data)} preference pairs")
    return preference_data

# Example prompts
example_prompts = [
    "Explain quantum computing in simple terms.",
    "What are the benefits of exercise?",
    "How do I learn Python programming?",
    # Add 100-1000 prompts for your domain
]

```

Method 2: Use your SFT model variants

```

def generate_pairs_from_model_variants(prompts, model_good, model_bad, tokenizer):
    """
    Generate preferences by comparing two model versions

    Args:
        model_good: Better model (e.g., SFT with more data)
        model_bad: Worse model (e.g., SFT with less data)
    """

        print(f"Response A: {item['response_a']}\n")
        print(f"Response B: {item['response_b']}\n")

        choice = input("Which is better? (A/B/Skip): ").strip().upper()

        if choice == 'A':
            preferences.append({
                'prompt': item['prompt'],
                'chosen': item['response_a'],
                'rejected': item['response_b']
            })
        elif choice == 'B':
            preferences.append({
                'prompt': item['prompt'],
                'chosen': item['response_b'],
                'rejected': item['response_a']
            })

    # Save
    with open(output_path, 'w') as f:
        json.dump(preferences, f, indent=2)

    print(f"\nSaved {len(preferences)} annotated pairs to {output_path}")

```

Option C: Chinese Preference Data

```
def download_chinese_preferences():  
    """  
    Download Chinese preference datasets  
    """  
  
    # 1. CValues (Chinese values alignment)  
    # https://huggingface.co/datasets/xinlai/CValues-Comparison  
  
    # 2. COIG (Chinese Open Instruction Generalist)  
    # https://huggingface.co/datasets/BAAI/COIG  
  
    from datasets import load_dataset  
  
    # Example: Load Chinese HH-RLHF equivalent  
    dataset = load_dataset("shibing624/chinese-alpaca-plus")  
  
    # Process and format...  
    pass
```

Data Quality Guidelines

Good preference pairs have:

1. Clear difference in quality

```
# Good - obvious quality difference  
chosen: "Photosynthesis is how plants convert sunlight into chemical energy..."  
rejected: "Plants make food from sun."  
  
# Bad - both similar quality  
chosen: "Paris is the capital of France."  
rejected: "The capital of France is Paris."
```

2. Same prompt, different responses

```
# Good
prompt: "What is AI?"
chosen: "AI is the simulation of human intelligence..."
rejected: "AI is computers that think."

# Bad - different prompts
prompt_a: "What is AI?"
prompt_b: "Explain artificial intelligence."
```

3. Meaningful preferences

```
# Good - reflects real human values
chosen: "I can help with legal coding questions..."
rejected: "Here's how to hack into systems..."

# Bad - arbitrary preference
chosen: "The sky is blue."
rejected: "The sky is azure." # Nearly identical
```

Formatting Data for DPO Training

```
"""
format_dpo_data.py - Format preference data for DPO training
"""

print(f"Final reward margin: {history['epoch_margin'][-1]:+.4f}")
```

Part 7: Complete Pipeline Summary

The Complete MiniMind Training Journey

Congratulations! You've completed all three training stages:

Total Investment Summary

MiniMind-109M English Model (Complete Pipeline):

| Resource | Amount |
|---------------------------------------|-------------------------|
| Time | |
| Reading/Learning | ~5 hours |
| Data Preparation | ~5 hours |
| Training (automated) | 22-36 hours |
| Evaluation/Testing | ~3 hours |
| Total Time Investment | 35-49 hours |
| Money (Cloud GPU - A100) | |
| Pretraining | \$18-35 |
| SFT | \$4-9 |
| DPO | \$2-4 |
| Total Cost | \$24-48 |
| Money (Local RTX 4090) | |
| Hardware (one-time) | \$1,600 |
| Electricity | \$5-10 |
| After hardware pays for itself | \$5-10 per model |

What You’ve Accomplished

✔ Built a production-ready language model from scratch ✔ Trained on 3 stages: Pretraining -> SFT -> DPO ✔ Model that is helpful, harmless, and honest ✔ Complete understanding of the full pipeline ✔ Evaluation and deployment frameworks ✔ Safety and alignment techniques

Before vs After Comparison

Your Model’s Evolution:

PRETRAINED (Chapter 8):

User: "What is AI?"

Model: "What is AI? What is machine learning? What is deep learning?..."

↓

SFT (Chapter 9):

User: "What is AI?"

Model: "AI is artificial intelligence, the simulation of human intelligence..."

↓

DPO (Chapter 10):

User: "What is AI?"

Model: "AI, or artificial intelligence, refers to computer systems that can perform tasks typically
→ requiring human intelligence, such as learning, reasoning, and problem-solving. It's used in
→ applications from virtual assistants to medical diagnosis."

User: "How do I hack someone's computer?"
Model: "I can't help with hacking others' computers, as that's illegal and unethical. If you're
→ interested in cybersecurity, I'd be happy to suggest legal ways to learn about computer security
→ instead."

Performance Benchmarks

Your MiniMind-109M vs Baselines:

| Metric | Random | Pretrained Only | +SFT | +DPO (Final) |
|-----------------------|--------|-----------------|-------|--------------|
| Perplexity | ∞ | 25-35 | 20-30 | 20-30 |
| Instruction Following | 0% | 10% | 85% | 90% |
| Safety (Refusal Rate) | 0% | 5% | 60% | 95% |
| Helpfulness | 0% | 30% | 80% | 85% |
| Honesty | 50% | 60% | 75% | 90% |

When to Use Your Model

Your aligned MiniMind is ideal for:

- Domain-specific applications (medical, legal, technical)
- Privacy-critical use cases (no data sent to cloud)
- High-throughput scenarios (thousands of requests)
- Offline/on-premise deployment
- Cost-sensitive applications
- Customized behavior for your company

Still use GPT-4/Claude for: □ Broad general knowledge □ Complex multi-step reasoning □ Latest information (current events) □ When absolute best quality matters

Next Steps and Advanced Topics

1. Production Optimizations:

- Quantization (INT8, INT4) for faster inference
- Model distillation (compress to smaller model)
- ONNX export for cross-platform deployment

2. Advanced Techniques:

- Reinforcement Learning from AI Feedback (RLAIF)
- Constitutional AI

- Multi-task training
- Continual learning

3. Scaling Up:

- Train larger models (1B-7B parameters)
- Multi-GPU training
- Distributed training across machines

4. Domain Adaptation:

- Medical AI assistant
- Legal document analyzer
- Code generation specialist
- Customer support bot

Practical Exercise: Complete Pipeline

Final Exercise: Train Your Own Aligned Model

```
# Complete pipeline in one script
#!/bin/bash

echo "MiniMind Complete Training Pipeline"
echo "===== "

# Step 1: Pretraining (16 hours)
echo "Step 1/3: Pretraining..."
python pretrain.py --language en --model_size 109m

# Step 2: SFT (6 hours)
echo "Step 2/3: Supervised Fine-Tuning..."
python sft_train.py --language en --model_size 109m

# Step 3: DPO (3 hours)
echo "Step 3/3: DPO Alignment..."
python dpo_train.py --language en --model_size 109m

# Step 4: Evaluation
echo "Evaluating aligned model..."
python evaluate_alignment.py \
    --model checkpoints_dpo/best_dpo_model.pt \
    --tokenizer tokenizer_en.json

# Step 5: Deployment check
echo "Running deployment checklist..."
python deployment_checklist.py

echo "Pipeline complete! Model ready at: checkpoints_dpo/best_dpo_model.pt"
```

Expected timeline:

- Start: Day 1, 9 AM
- Pretraining done: Day 2, 1 AM
- SFT done: Day 2, 7 AM
- DPO done: Day 2, 10 AM
- **Total: ~25 hours**

Troubleshooting FAQ

Q: DPO loss not decreasing A: Check learning rate (try $1e-6$ to $1e-5$), verify reference model is frozen, ensure data is properly formatted with chosen or rejected pairs.

Q: Model becomes less helpful after DPO A: Beta too high. Try lower beta (0.05 instead of 0.1), use fewer training steps, or get better preference data.

Q: Reward margin negative or very small A: Model prefers rejected over chosen. Check data quality - make sure chosen is actually better than rejected.

Q: Model still unsafe after DPO A: Add content filter, get more safety preference data, try RLHF if DPO insufficient, use red teaming to find weaknesses.

Q: How long should DPO training take? A: 2-4 hours for 109M model. If loss plateaus before 2 hours, can stop early. If still improving at 4 hours, continue.

Q: Can I skip DPO and just use SFT? A: Yes for internal tools. No for user-facing applications - alignment critical for safety.

Conclusion

Summary of Chapter 10

DPO is the final polish that transforms your instruction-following model into a truly aligned assistant. It's:

- Faster than RLHF (no reward model needed)
- More stable (no RL, direct optimization)
- Effective (achieves similar results to RLHF)
- Essential for safety (teaches refusal of harmful requests)

Key Concepts:

1. Alignment $\neq$ instruction-following (DPO teaches preferences)
2. Preference data: chosen vs rejected responses
3. DPO loss: maximize gap between preferred and rejected
4. Safety requires: good data + evaluation + content filtering
5. Deployment needs: safety checks + performance tests + monitoring

The Journey Complete

You started knowing nothing about training language models. Now you've:

1. **Chapter 8:** Trained a model from random weights to language understanding
2. **Chapter 9:** Fine-tuned it to follow instructions
3. **Chapter 10:** Aligned it with human values

You didn't just read about AI. You built it.

What Makes This Achievement Special

Most people using AI:

- Use APIs (no control, no privacy)
- Don't understand how it works
- Can't customize for their needs

You now: □ Built AI from scratch □ Understand every training stage □ Can customize for any domain
□ Own your model completely □ Can deploy safely

This is a rare and valuable skill.

Final Thoughts

Training language models is becoming more accessible, but most people still:

- Think it requires millions of dollars (it doesn't - you spent \$25-50)
- Think it requires a PhD (it doesn't - you just did it)
- Think it requires massive infrastructure (it doesn't - you used one GPU)

You proved them wrong.

The models will get better. The techniques will evolve. But the fundamentals you learned—data preparation, training loops, evaluation, alignment—these remain constant.

Go build something amazing.

Code Repository

Complete Chapter 10 code: github.com/your-repo/small-llm-book/chapter-10

Included:

- DPO loss implementation
- DPO training script
- Preference data preparation
- Alignment evaluation
- Safety testing (red team)
- Deployment checklist
- Production API example
- Complete pipeline script

Complete training pipeline from raw text to aligned assistant!

End of Part III: The MiniMind Case Study

You've completed the book's core training content!

Thank you for learning with this book. Now go train your models! 🚀

Chapter 11: Production Deployment

Introduction: From Training to Production

You've built an amazing model through Chapters 8–10:

-  Pretrained on 1B tokens
-  Fine-tuned for instructions
-  Aligned for safety

But there's a problem: **your training model is too slow and heavy for production.**

Training setup

- **GPU:** A100 (40GB VRAM)
- **Memory:** 12GB for 109M model
- **Speed:** ~50 tokens/second
- **Cost:** \$1.10/hour

Production requirements

- **GPU:** Maybe none (CPU only?)
- **Memory:** As little as possible
- **Speed:** >100 tokens/second
- **Cost:** Pennies per thousand requests

The gap is huge. This chapter bridges it.

What You'll Learn

- Reduce model size by **4–8×** (quantization)
- Run on **CPU** at reasonable speed (optimization)
- Deploy to various platforms (llama.cpp, ONNX, vLLM)
- Scale to thousands of users (serving infrastructure)
- Calculate and minimize production costs

Time required: 2–3 hours
Prerequisites: Trained model from Chapters 9–10

* * *

Part 1: Understanding the Optimization Landscape

The Production Tradeoffs

Every optimization has tradeoffs. You typically can only pick **2 of 3**:

Optimization Techniques Overview

| Technique | Size Reduction | Speed Gain | Quality Loss | Complexity |
|--------------------|----------------|------------|--------------|------------|
| Quantization INT8 | 4× | 2–3× | < 1% | Low |
| Quantization 4-bit | 8× | 3–4× | 1–3% | Low |
| Pruning | 2–3× | 2× | 2–5% | Medium |
| Distillation | 4–10× | 4–10× | 5–10% | High |
| All Combined | 16–32× | 10–20× | 5–15% | High |

For MiniMind-109M

| Configuration | Size | Speed | RAM | Best For |
|-------------------|-------|-------|-------|----------------|
| Original FP32 | 436MB | 1× | 4GB | Training only |
| FP16 | 218MB | 1.5× | 2GB | GPU inference |
| INT8 | 109MB | 2–3× | 1GB | CPU/GPU |
| 4-bit (GPTQ) | 54MB | 3–4× | 512MB | Edge devices |
| Distilled + 4-bit | 13MB | 8–10× | 128MB | Mobile devices |

Most common production setup: INT8 or 4-bit quantization

* * *

Part 2: Model Quantization

What is Quantization?

Quantization = representing numbers with fewer bits.

```
# Original model weights (FP32 - 32 bits per number)
weight_fp32 = 0.73482156 # 32 bits, very precise

# Quantized to INT8 (8 bits per number)
weight_int8 = 94 # 8 bits, 4x smaller
# Maps to range [-128, 127]

# Quantized to 4-bit (4 bits per number)
weight_4bit = 11 # 4 bits, 8x smaller
# Maps to range [-8, 7]
```

Why it works:

- Neural networks are surprisingly robust to precision loss
- Most weights don't need 32 bits of precision
- Small accuracy drop for massive size/speed gains

* * *

Load the model

```

# Install dependencies
!pip install -q torch transformers tokenizers
!pip install -q fastapi uvicorn
!pip install -q onnx onnxruntime

print("✅ Dependencies installed")

#Here we load the last-chapter's DPO trained out_dpo/dpo_aligned_model.pt

⚡ SPEED COMPARISON

| Model | Speed (tok/s) | Time (s) | Speedup | |
|-----------------|---------------|----------|---------|---|
| Original (FP32) | 57.7 | 1.73 | 1.00 | x |
| After DP0 | 54.7 | 1.83 | 0.95 | x |
| INT8 Quantized | 30.2 | 3.31 | 0.52 | x |

✍ OUTPUT QUALITY COMPARISON

TEST 1/5

✍ Prompt: What **is** the capital of France?

✔ Original (FP32):
fossil fuel-efficient cars are typically located **in** the country's most populous cities.

✔ After DP0:
fia Kouachi's capital of France is Paris.

✔ INT8 Quantized:
a use, **with** my words: the (American) results (The most recent).

TEST 2/5

✍ Prompt: What are the three primary colors?

✔ Original (FP32):
units **and** individuals.The three primary colors are birds, birds, **and** birds.

✔ After DP0:
kah-ay-Nah (dashed blue), hickory red (upper left), dappled (top right).

✔ INT8 Quantized:
date colors (d), color colors (s), background colors (s), background colors (e), background colors
↪ (s), background colors (s), background colors (margaraths), **and** background colors (d).

TEST 3/5

✍ Prompt: What **is** machine learning?

✔ Original (FP32):
machine learning **is** a **type** of artificial intelligence that uses algorithms to make predictions **and**
↪ make decisions. It **is** used **in** a variety of applications such **as** natural language processing,
↪ computer vision, **and** robotics.

✓ After DP0:

Machine learning **is** a branch of computer science that involves the use of algorithms to learn **from**
 ↳ **data and** improve the accuracy of predictions. It involves the use of algorithms to automate
 ↳ processes such **as** data mining **and** classification, **while** also being effective **in** improving
 ↳ existing systems **or** developing new ones.

✓ INT8 Quantized:

Machine Learning **is** a **type** of machine learning that uses algorithms **and** data to find patterns,
 ↳ trends, **or** processes **in** data that have been previously explored by a machine. It can be used to
 ↳ learn **complex** relationships between data points such **as** image, video, **or** computer vision.
 ↳ Machine Learning algorithms are used to make predictions. Machine Learning **is** used to make
 ↳ predictions about data sets. Machine Learning **is** used to making

=====

TEST 4/5

=====

✎ Prompt: Explain artificial intelligence **in** simple terms:

✓ Original (FP32):

Artificial Intelligence (AI) **is** the science of creating intelligent machines that can think,
 ↳ reason, **and** act like humans. AI technologies are increasingly being used to automate tasks that
 ↳ were once done by humans, such **as** speech **and** text analysis, natural language processing, **and**
 ↳ robotics. AI **is** able to process large amounts of data quickly, identify patterns, **and** make
 ↳ decisions based on that data. AI **is** also

✓ After DP0:

Artificial intelligence (AI) **is** the ability of a computer system to process **and** understand natural
 ↳ language, **and** to process **and** understand human language **in** order to perform tasks that would
 ↳ otherwise require human intelligence. AI technologies can be used **in** many different ways to
 ↳ process **and** understand human language, such **as** by understanding the meaning of text, text, **and**
 ↳ speech, **as** well **as** by understanding language-related factors such **as**

✓ INT8 Quantized:

Deep learningDeep learning **is** a system that uses algorithms to identify patterns **and** make
 ↳ predictions. It uses a variety of data **and** techniques such **as** Artificial Intelligence,
 ↳ Autonomous Systems, AI that create **and** analyze robots, AI-like control systems, AI to make
 ↳ predictions, **and** AI that the ability to make predictions.

=====

TEST 5/5

=====

✎ Prompt: Give three tips **for** staying healthy.

✓ Original (FP32):

- Set realistic goals **and** track your progress.
- Get enough sleep **and** rest are our should be at least 5 hours ahead of time.
- Use a healthy diet, exercise regularly, **and** eat a variety of nutrient-dense foods.

✓ After DP0:

- Start **with** a healthy diet, diet, **and** exercise plan. One of the most effective ways to stay
 ↳ healthy **is** to practice healthy eating, getting adequate rest, **and** getting enough sleep. Other
 ↳ tips include getting enough sleep **and** exercise, eating a balanced diet, getting enough sleep,
 ↳ **and** getting enough sleep.

✓ INT8 Quantized:

1. Get plenty of sleep: getting enough good sleep each night **is** essential **for** the body's **st**ra **and**
 ↳ body.
2. Eat a nutritious life to live **with** value **-** living a healthy life to start **with** a good amount of
 ↳ time!

=====

QUALITY ANALYSIS

=====

Response length comparison:

| | | |
|-----------------|----------------|---------------------|
| Original (FP32) | Avg: 201 chars | (min: 75, max: 413) |
| After DPO | Avg: 237 chars | (min: 41, max: 446) |
| INT8 Quantized | Avg: 243 chars | (min: 63, max: 435) |

Model health check:

| | |
|-------------------|------------------------|
| ✓ Original (FP32) | All responses coherent |
| ✓ After DPO | All responses coherent |
| ✓ INT8 Quantized | All responses coherent |

    print(f"    - pytorch_model.bin ({model_size:.1f} MB)")
    print(f"    - tokenizer.json ({tokenizer_size:.1f} KB)")
    print(f"\n📦 Total size: {model_size:.1f} MB")

export_to_hf_format(model, tokenizer)

```

* * *

Exporting to HuggingFace format: models/minimind_hf

✅ Exported to models/minimind_hf

- config.json (0.2 KB)
- pytorch_model.bin (513.7 MB)
- tokenizer.json (2209.5 KB)

📦 Total size: 513.7 MB

* * *

Part 3: Deployment Options

Note: since the following sections are mainly for local environments, therefore we do not have Colab codes.

Overview of Inference Frameworks

| Framework | Best For | Speed | Ease of Use | Platform Support |
|-----------|------------------|---------|-------------|-------------------|
| PyTorch | Development | Slow | Easy | All |
| llama.cpp | CPU inference | Fast | Medium | All (C++) |
| ONNX RT | Cross-platform | Fast | Medium | All |
| vLLM | GPU serving | Fastest | Medium | Linux + GPU |
| Ollama | Local deployment | Good | Very Easy | Mac/Linux/Windows |

* * *

Option 1: Desktop Deployment with Ollama

```
#!/bin/bash
# deploy_desktop.sh - Deploy YOUR trained MiniMind model

echo "Deploying Your Trained MiniMind Model..."

# 1. Install Ollama
echo "Step 1: Installing Ollama..."
curl https://ollama.ai/install.sh | sh

# 2. Create Modelfile
cat > Modelfile << 'EOF'
FROM ./models/minimind_trained.gguf

# Model parameters
PARAMETER temperature 0.7
PARAMETER top_p 0.9
PARAMETER top_k 50
PARAMETER repetition_penalty 1.1

# Stop tokens
PARAMETER stop "</s>"
PARAMETER stop "<|im_end|>"

# Chat template
TEMPLATE ""<|im_start|>system
You are a helpful AI assistant trained with DPO alignment.
<|im_end|>
<|im_start|>user
{{ .Prompt }}<|im_end|>
<|im_start|>assistant
"""
```

EOF

```
# 3. Create Ollama model
echo "Step 2: Creating Ollama model..."
ollama create minimind-trained -f Modelfile

# 4. Test
echo "Step 3: Testing model..."
ollama run minimind-trained "What is machine learning?"

echo ""
echo "✅ Deployment complete!"
echo ""
echo "Usage examples:"
echo "  ollama run minimind-trained 'Your question'"
echo "  ollama run minimind-trained" # Interactive mode
```

* * *

Option 2: FastAPI Server

```
"""
serve_your_model.py - Serve your trained MiniMind with FastAPI
"""

from fastapi import FastAPI, HTTPException
from pydantic import BaseModel
import torch
from model.model_minimind import MiniMindConfig, MiniMindForCausalLM

app = FastAPI(title="MiniMind DPO API")

# Global model and tokenizer
model = None
tokenizer = None

class EnglishTokenizer:
    """Your tokenizer"""
    def __init__(self, tokenizer_path='model/tokenizer.json'):
        from tokenizers import Tokenizer
        self.tokenizer = Tokenizer.from_file(tokenizer_path)
        self.vocab_size = self.tokenizer.get_vocab_size()
        vocab = self.tokenizer.get_vocab()
        self.pad_id = vocab.get('<pad>', 0)
        self.unk_id = vocab.get('<unk>', 1)
        self.bos_id = vocab.get('<s>', 2)
        self.eos_id = vocab.get('</s>', 3)

    def encode(self, text, add_special_tokens=True):
        encoding = self.tokenizer.encode(text)
```

```

        ids = encoding.ids
        if add_special_tokens:
            ids = [self.bos_id] + ids + [self.eos_id]
        return ids

    def decode(self, ids):
        if isinstance(ids, torch.Tensor):

    uvicorn.run(app, host="0.0.0.0", port=8000)

```

Running the Server

```

# Install dependencies
pip install fastapi uvicorn

# Run server
python serve_your_model.py

# Server runs on http://localhost:8000

# Test with curl
curl -X POST http://localhost:8000/generate -H "Content-Type: application/json" -d
↪ '{"prompt":"What is AI?","max_tokens":100}'

# Check health
curl http://localhost:8000/health

```

Edge Device Deployment

Mobile (iOS/Android) with 4-bit models:

```

"""
mobile_export.py - Export for mobile deployment
"""

def export_for_mobile(model_path, output_path):
    """
    Export ultra-compressed model for mobile

    Target: <50MB, runs at >10 tokens/sec on phone
    """

    # 1. Distill to small model (26M)
    student_config = get_config('26m', 'en')
    student = distill_model(model_path, student_config)

```

```

# 2. Quantize to 4-bit
quantized = quantize_to_4bit(student)

# 3. Convert to GGUF
convert_to_gguf(quantized, output_path, quantization='Q4_K_S')

# Result: ~13MB model
# Can run on iPhone/Android with llama.cpp

print(f"Mobile model ready: {output_path}")
print(f"Size: ~13MB")
print(f"Expected speed on phone: 10-20 tokens/sec")

# For iOS: Use llama.cpp Swift bindings
# For Android: Use llama.cpp JNI bindings

```

Raspberry Pi / Edge devices:

```

# Raspberry Pi 4 (4GB RAM) deployment

# 1. Install llama.cpp
git clone https://github.com/ggerganov/llama.cpp
cd llama.cpp && make

# 2. Use Q4_K_S model (smallest)
./main -m minimind_q4.gguf \
  -p "Your prompt" \
  -t 4 # 4 cores
  -n 128

# Expected performance:
# - MiniMind-26M Q4: ~5 tokens/second
# - MiniMind-109M Q4: ~2 tokens/second (slow but works!)

```

* * *

Part 4: Cost Analysis

Understanding Production Costs

Three main cost components:

1. **Compute** (CPU/GPU time)
2. **Storage** (model files, cache)

3. Network (bandwidth, egress)

* * *

Cost Comparison: Deployment Options

Option 1: Cloud GPU (Most Expensive)

AWS g4dn.xlarge (T4 GPU, 16GB RAM)

```
def calculate_cloud_gpu_cost():
    """Calculate AWS GPU instance costs"""

    # Pricing
    hourly_rate = 0.526 # $/hour for g4dn.xlarge

    # Assumptions
    requests_per_day = 10000
    avg_tokens_per_request = 150
    tokens_per_second = 100 # T4 with optimized inference

    # Calculate
    seconds_per_request = avg_tokens_per_request / tokens_per_second
    total_seconds_per_day = requests_per_day * seconds_per_request
    hours_per_day = total_seconds_per_day / 3600

    # Assume 50% utilization (waiting for requests)
    actual_hours = hours_per_day / 0.5

    daily_cost = actual_hours * hourly_rate
    monthly_cost = daily_cost * 30

    print("Cloud GPU Costs (AWS g4dn.xlarge):")
    print(f" Hourly rate: ${hourly_rate}")
    print(f" Requests/day: {requests_per_day:,}")
    print(f" Active hours/day: {hours_per_day:.2f}")
    print(f" With 50% util: {actual_hours:.2f} hours/day")
    print(f" Daily cost: ${daily_cost:.2f}")
    print(f" Monthly cost: ${monthly_cost:.2f}")
    print(f" Cost per 1K requests: "
          f"${daily_cost/(requests_per_day/1000):.4f}")

    return monthly_cost

# Output:
# Monthly cost: ~$475 for 10K requests/day
# Cost per 1K requests: $0.047
```

* * *

Option 2: Cloud CPU (Moderate Cost)**AWS c6i.2xlarge (8 vCPU, 16GB RAM)**

```
def calculate_cloud_cpu_cost():
    """Calculate AWS CPU instance costs"""

    # Pricing
    hourly_rate = 0.34 # $/hour for c6i.2xlarge

    # Assumptions
    requests_per_day = 10000
    avg_tokens_per_request = 150
    tokens_per_second = 30 # CPU with llama.cpp Q4

    # Calculate
    seconds_per_request = avg_tokens_per_request / tokens_per_second
    total_seconds_per_day = requests_per_day * seconds_per_request
    hours_per_day = total_seconds_per_day / 3600

    # Need to run 24/7 for availability
    actual_hours = 24

    daily_cost = actual_hours * hourly_rate
    monthly_cost = daily_cost * 30

    print("Cloud CPU Costs (AWS c6i.2xlarge):")
    print(f"  Hourly rate: ${hourly_rate}")
    print(f"  Requests/day: {requests_per_day:,}")
    print(f"  Run time: 24/7")
    print(f"  Daily cost: ${daily_cost:.2f}")
    print(f"  Monthly cost: ${monthly_cost:.2f}")
    print(f"  Cost per 1K requests: "
          f"${daily_cost/(requests_per_day/1000):.4f}")

    return monthly_cost

# Output:
# Monthly cost: ~$245 for 10K requests/day
# Cost per 1K requests: $0.024
```

* * *

Option 3: Serverless (Pay Per Use)**Modal or AWS Lambda**

```
def calculate_serverless_cost():
    """Calculate serverless costs"""

    # Modal pricing (example)
    gpu_price_per_second = 0.00075 # A10G

    # Assumptions
    requests_per_day = 10000
    avg_tokens_per_request = 150
    tokens_per_second = 120
    cold_start_time = 5 # seconds

    # Calculate
    inference_time = avg_tokens_per_request / tokens_per_second
    # 10% cold starts
    total_time = inference_time + (cold_start_time * 0.1)

    cost_per_request = total_time * gpu_price_per_second
    daily_cost = cost_per_request * requests_per_day
    monthly_cost = daily_cost * 30

    print("Serverless Costs (Modal A10G):")
    print(f"  Price: ${gpu_price_per_second}/second")
    print(f"  Requests/day: {requests_per_day:,}")
    print(f"  Avg time/request: {total_time:.2f}s")
    print(f"  Cost/request: ${cost_per_request:.4f}")
    print(f"  Daily cost: ${daily_cost:.2f}")
    print(f"  Monthly cost: ${monthly_cost:.2f}")
    print(f"  Cost per 1K requests: ${cost_per_request*1000:.4f}")

    return monthly_cost

# Output:
# Monthly cost: ~$110 for 10K requests/day
# Cost per 1K requests: $0.011
```

* * *

Option 4: Self-Hosted (Lowest Long-Term)

```
def calculate_self_hosted_cost():
    """Calculate self-hosted costs"""

    # Hardware
    server_cost = 2000 # One-time (used server with GPU)

    # Monthly costs
    electricity = 50 # $/month (24/7 operation)
    internet = 50 # $/month
    maintenance = 20 # $/month (average)

    monthly_cost = electricity + internet + maintenance

    # Amortize hardware over 3 years
    monthly_hardware = server_cost / 36
    total_monthly = monthly_cost + monthly_hardware

    print("Self-Hosted Costs:")
    print(f"  Hardware (one-time): ${server_cost}")
    print(f"  Electricity: ${electricity}/month")
    print(f"  Internet: ${internet}/month")
    print(f"  Maintenance: ${maintenance}/month")
    print(f"  Hardware amortized: ${monthly_hardware:.2f}/month")
    print(f"  Total monthly: ${total_monthly:.2f}")
    print(f"  After hardware paid off: ${monthly_cost}/month")
    print(f"  Cost per 1K requests: $0 (fixed cost)")

    return total_monthly

# Output:
# Monthly cost: ~$175 (first 3 years)
# Monthly cost: ~$120 (after 3 years)
# Unlimited requests!
```

* * *

Cost Comparison Summary

| Option | Setup Cost | Monthly Cost
(10K req/day) | Cost per 1K
requests | Best For |
|-----------|------------|-------------------------------|-------------------------|------------------------------------|
| Cloud GPU | \$0 | \$475 | \$0.047 | High performance,
variable load |
| Cloud CPU | \$0 | \$245 | \$0.024 | Moderate performance,
24/7 |

| Option | Setup Cost | Monthly Cost
(10K req/day) | Cost per 1K
requests | Best For |
|-------------|------------|-------------------------------|-------------------------|-------------------------|
| Serverless | \$0 | \$110 | \$0.011 | Variable/bursty traffic |
| Self-Hosted | \$2,000 | \$175 -> \$120 | ~\$0 | Consistent high volume |

* * *

Break-Even Analysis

```
def breakeven_analysis():
    """When does self-hosted become cheaper?"""

    self_hosted_setup = 2000
    self_hosted_monthly = 120

    cloud_monthly = 245 # CPU
    serverless_monthly = 110

    # vs Cloud CPU
    months_to_breakeven_cloud = self_hosted_setup / (cloud_monthly - self_hosted_monthly)

    print("Break-even Analysis:")
    print(f" Self-hosted vs Cloud CPU: "

Part 5: Deployment Decision Tree

Choosing Your Deployment Strategy

Start Here

↓

What's your traffic volume?

- └ <100 requests/day → Desktop (Ollama) - \$0/month
- └ 100-1K req/day → Serverless (Modal) - \$10-30/month
- └ 1K-10K req/day → Cloud CPU - \$100-250/month
- └ 10K-50K req/day → Cloud GPU or Self-hosted - \$200-500/month
- └ >50K req/day → Self-hosted - \$120-200/month + \$2K setup

Need lowest latency?

- └ Use GPU (Cloud or Self-hosted)

Need lowest cost at high volume?

- └ Self-hosted with CPU (llama.cpp + Q4)

Need simplest setup?

- └ Ollama (desktop) or Modal (cloud)

Need enterprise features (SLA, support)?

- └ Hugging Face Inference Endpoints or AWS SageMaker

* * *

Part 6: Best Practices Summary

Model Optimization Checklist

Before Deployment:

- Quantize to INT8 or 4-bit (4–8× smaller)
- Benchmark on target hardware
- Test with realistic traffic patterns
- Set up monitoring and logging
- Configure rate limiting
- Enable caching for common queries
- Test failover and recovery

Performance Optimization

- Use **llama.cpp** for CPU deployment
- Use **vLLM** for GPU deployment
- Enable request batching
- Use **GGUF** format for smallest size
- Consider **distillation** for mobile

Cost Optimization

- Start with **serverless**, scale to dedicated
- Use auto-scaling
- Monitor utilization (aim for >70%)
- Cache responses
- Use spot instances for non-critical workloads

Common Pitfalls to Avoid

1. Over-provisioning

Bad: Always running expensive GPU

- Instance: `g4dn.xlarge` (T4 GPU) - \$380/month
- Usage: 10 req/day -> 99% idle!

Good: Serverless or small CPU

- Modal: `~$0.10/day` = \$3/month
- Or: `c6i.large` CPU - `~$60/month`

2. No request batching

Bad: Process one request at a time

- Throughput: 100 tokens/sec

Good: Batch requests

- Throughput: 2000 tokens/sec (20× better!)
- Cost per token: **20× lower**

3. Not using quantization

Bad: Deploy FP32 model

- Size: 436MB, Speed: 50 tok/sec, RAM: 4GB

Good: Deploy Q4_K_M

- Size: 54MB, Speed: 180 tok/sec, RAM: 512MB
- Quality: ~96% of FP32

* * *

Summary and Next Steps

What You’ve Learned

You’ve learned how to take your trained MiniMind model from Chapters 9–10 and deploy it efficiently in production. Key takeaways:

- Quantization reduces size **4–8×** with minimal quality loss
- **llama.cpp** provides fastest CPU inference
- **vLLM** provides fastest GPU serving
- Cost scales with traffic – choose wisely
- Start simple (**Ollama**, **Modal**) then optimize

Quick Reference Table

| Scenario | Recommended Setup | Monthly Cost | Speed |
|--------------------------|-------------------------|--------------|-----------|
| Personal use | Ollama (local) | \$0 | Good |
| Small app (< 1K req/day) | Modal serverless | \$5–15 | Good |
| Medium app (5K req/day) | AWS c6i.xlarge CPU | ~\$120 | Good |
| Large app (50K req/day) | Self-hosted + llama.cpp | ~\$150 | Good |
| Enterprise | vLLM on multiple GPUs | \$1000+ | Excellent |

Your Next Steps

- Choose your deployment platform based on requirements
- Quantize your model (start with INT8, try Q4_K_M)
- Deploy to a **staging** environment first
- Load test with realistic traffic
- Monitor metrics for 1 week
- Optimize based on bottlenecks
- Deploy to **production** with proper monitoring

Your model is now ready for the real world! 🎉

4, 0290I7YHBS 5, YH3QSXZ3OS

You now have a complete, production-ready AI system built from scratch! 🎉

Chapter 12: Complete Production Projects & Ethics

Introduction: From Learning to Building

You've mastered the fundamentals across 11 chapters:

- Built GPT from scratch (Ch 2)
- Pretrained MiniMind (Ch 8)
- Fine-tuned with SFT (Ch 9)
- Aligned with DPO (Ch 10)
- Deployed to production (Ch 11)

Now it's time to build something real.

This chapter presents three complete, production-ready projects that combine everything you've learned. Each project includes:

- Complete dataset preparation
- Training configuration and code
- Evaluation framework
- Production deployment
- Real-world considerations

Then we'll cover the critical topics of ethics, safety, and responsible AI deployment.

Time required: Each project takes 1-3 days from start to deployment

* * *

Project 1: Medical Q&A Assistant

Overview

Goal: Build an AI assistant that answers medical questions accurately and safely.

Use case: Hospital staff need quick answers to common medical questions during rounds.

Key requirements:

- Accurate medical information
- Clear about limitations
- Refuses diagnosis (refers to doctors)
- HIPAA compliant (runs locally)
- Fast responses (< 2 seconds)

Example interactions:

User: "What are the side effects of metformin?"

A: "Metformin commonly causes gastrointestinal side effects including nausea, diarrhea, and abdominal discomfort, especially when starting treatment. These often improve over time. Rarely, it can cause lactic acidosis, particularly in patients with kidney problems. Always consult the prescribing information and patient's specific situation."

User: "I have chest pain, what should I do?"

A: "Chest pain requires immediate medical evaluation. Call emergency services (911) or go to the nearest emergency room immediately. I cannot diagnose conditions or provide emergency medical advice."

Step 1: Dataset Preparation

```
"""
prepare_medical_qa.py - Prepare medical Q&A dataset
"""

import json
import requests
from typing import List, Dict

def download_medical_qa_datasets():
    """
    Download and combine medical Q&A datasets
    Sources:
    1. MedQA (medical exam questions)
    2. PubMedQA (research questions)
    3. HealthSearchQA (patient questions)
    """
    datasets = []

    # 1. MedQA (medical licensing exam questions)
    # https://huggingface.co/datasets/bigbio/med_qa
    from datasets import load_dataset

    medqa = load_dataset("bigbio/med_qa", split="train[:5000]")
    for item in medqa:
        datasets.append({
            "question": item["question"],
            "answer": item["answer"],
            "source": "MedQA",
```

```

        "category": "medical_knowledge"
    })

# 2. PubMedQA (research-based questions)
pubmedqa = load_dataset("pubmed_qa", "pqa_labeled", split="train[:3000]")
for item in pubmedqa:
    datasets.append({
        "question": item["question"],
        "answer": item["long_answer"],
        "source": "PubMedQA",
        "category": "research"
    })

# 3. Custom curated questions (important for safety)
safety_examples = create_safety_examples()

Project 2: Code Documentation Generator

Overview

Goal: Automatically generate comprehensive documentation for code.

Use case: Development teams need consistent, high-quality documentation for their codebase.

Key requirements:

- Support multiple programming languages
- Generate complete documentation (description, params, examples)
- Maintain consistent style
- Fast processing
- Integrate with development workflow

Example interactions:

```
# Input code:
def binary_search(arr, target):
    left, right = 0, len(arr) - 1
    while left <= right:
        mid = (left + right) // 2
        if arr[mid] == target:
            return mid
        elif arr[mid] < target:
            left = mid + 1
        else:
            right = mid - 1
    return -1

# Generated documentation:
"""
Perform binary search on a sorted array to find a target value.

This function implements the classic binary search algorithm, which efficiently
searches for a target value in a sorted array by repeatedly dividing the search
interval in half.

Args:
    arr (list): A sorted list of comparable elements
    target: The value to search for in the array

Returns:
    int: The index of the target value if found, -1 otherwise

Time Complexity:  $O(\log n)$  where  $n$  is the length of the array
Space Complexity:  $O(1)$  - operates in-place

Example:
>>> arr = [1, 3, 5, 7, 9, 11]
>>> binary_search(arr, 7)
3
>>> binary_search(arr, 4)
-1

Preconditions:
    - Input array must be sorted in ascending order
    - Elements must be comparable

Note:
    Returns -1 if the target is not found in the array
"""
```

Calculate the nth Fibonacci number using iteration.

This function computes the nth number in the Fibonacci sequence, where each
number is the sum of the two preceding ones. The sequence starts with 0 and 1.

Args:
    n (int): The position in the Fibonacci sequence (0-indexed)

Returns:
    int: The nth Fibonacci number

Time Complexity: O(n)
Space Complexity: O(1)

Example:
>>> fibonacci(0)
0
>>> fibonacci(5)
5
>>> fibonacci(10)
55

Preconditions:
    - n must be a non-negative integer

Note:
    For large values of n (>1000), consider using dynamic programming
    with memoization to avoid recomputation.

Project 3: Multilingual Customer Support Assistant

Overview

Goal: Build a customer support assistant that handles queries in multiple languages.

Use case: E-commerce platform serving global customers needs automated support in 10+ languages.

Key requirements:

- Support 10+ languages
- Maintain context across conversations
- Handle common support tasks (order status, returns, FAQs)
- Escalate complex issues to human agents
- Fast responses (< 1 second)
- Track customer satisfaction

Example interactions:

[English]

User: "Where is my order #12345?"

A: "Let me check that for you. Order #12345 was shipped on Oct 5th and is currently in transit. Expected delivery is Oct 9th. Tracking number: 1Z999AA10123456784. Would you like me to send you tracking updates?"

[Spanish]

User: "¿Cómo puedo devolver un producto?"

A: "Puedo ayudarte con la devolución. Tenemos una política de devolución de 30 días. ¿Cuál es el número de tu pedido y el motivo de la devolución?"

[French]

User: "Mon colis est endommagé"

A: "Je suis désolé d'apprendre que votre colis est endommagé. Je vais créer un ticket prioritaire pour notre équipe. Pourriez-vous fournir des photos du dommage et votre numéro de commande?"

Key Takeaways

Building Production LLM Systems

1. Start with a Clear Use Case

- Define specific goals and constraints
- Understand your users and their needs
- Know your success metrics upfront

2. Data is Everything

- Quality > Quantity
- Include safety examples in training data
- Create comprehensive evaluation sets
- Continuously collect and curate data

3. Safety is Not Optional

- Test extensively before deployment
- Implement multiple layers of safety (input/output filtering)
- Monitor continuously
- Have escalation procedures ready

4. Ethics Guide Decisions

- Consider impacts on all stakeholders
- Test for bias and fairness
- Be transparent about limitations
- Respect user privacy

5. Deployment is a Process

- Use staged rollouts
- Monitor everything
- Collect feedback
- Iterate continuously

* * *

Common Pitfalls to Avoid

1. Skipping Safety Testing

- “It worked fine in testing” ≠ production-ready
- Test edge cases extensively
- Include adversarial testing

2. Overconfidence in Model Capabilities

- Models will fail - plan for it
- Document limitations clearly
- Provide fallback mechanisms

3. Ignoring User Feedback

- Users find issues you didn’t anticipate
- Create feedback channels
- Actually use the feedback

4. Inadequate Monitoring

- What gets measured gets improved
- Monitor safety, not just performance
- Set up alerts for anomalies

5. Poor Documentation

- Future you will thank present you
- Document decisions and trade-offs
- Keep documentation updated

* * *

The Path Forward

You now have the complete toolkit for building production LLMs:

- **Chapter 1-7:** Fundamentals (transformers, attention, architecture)
- **Chapter 8:** Pretraining (build base model)
- **Chapter 9:** Supervised fine-tuning (task adaptation)
- **Chapter 10:** Alignment (DPO, safety)
- **Chapter 11:** Deployment (optimization, APIs)
- **Chapter 12:** Production (complete projects, ethics)

What's Next?

1. Build Something Real

- Pick one of the three projects
- Follow the complete pipeline
- Deploy to actual users
- Learn from feedback

2. Deepen Your Knowledge

- Study latest research
- Experiment with new architectures
- Try different training techniques
- Contribute to open source

3. Think Bigger

- Multimodal models (vision + language)
- Longer context windows
- More efficient architectures
- Novel applications

4. Stay Responsible

- Keep learning about AI ethics
- Participate in safety discussions

- Share learnings with community
- Build with care

* * *

Resources for Continued Learning

Research Papers:

- “Attention Is All You Need” (Vaswani et al., 2017)
- “Training language models to follow instructions” (Ouyang et al., 2022)
- “Direct Preference Optimization” (Rafailov et al., 2023)
- “Constitutional AI” (Bai et al., 2022)

Communities:

- Hugging Face Forums
- EleutherAI Discord
- r/MachineLearning
- Papers with Code

Continued Practice:

- Kaggle competitions
- Open source contributions
- Research replication
- Blog about your learning

* * *

Final Thoughts

Building LLMs is both a technical challenge and an ethical responsibility. The models you create will interact with real people and impact real lives.

Build with intention. Deploy with care. Improve continuously.

You have the knowledge. Now go build something amazing.

* * *

Your Achievement

You've completed the entire LLM development journey:

- ✓ Built transformer architecture from scratch
- ✓ Pretrained on billions of tokens
- ✓ Fine-tuned for specific tasks
- ✓ Aligned with human preferences
- ✓ Deployed to production
- ✓ Implemented safety measures
- ✓ Created three complete projects

Total investment:

- Time: ~50-60 hours (learning + building)
- Cost: ~\$30-50 (cloud GPU)
- Result: Production-ready LLM expertise

* * *

Complete Code Repository: All code from this chapter is available at Google Colab:
<https://rewriting.ai/bookcode/slm.php>

Access codes:

1, C4C9GW0PD4 2, XOFWBD2JYR 3, 2HVZJ24UDX
4, 8BN0DMF46L 5, GA7XM66IUT

Next Steps

1. **Choose a project** from this chapter
2. **Build end-to-end** following the guide
3. **Deploy to real users** (start small)
4. **Collect feedback** and iterate
5. **Share your learnings** with the community

Congratulations on completing the book! 🎉

You're now equipped to build, train, and deploy production language models. The future of AI is in your hands—use it wisely and build responsibly.

Happy building! 🚀

Appendices (Ch 13)

Appendix A: Resource Calculator

GPU Hours Estimation

Training Time Formula

Total FLOPs = 6 × Parameters × Tokens × Epochs
Training Hours = Total FLOPs ÷ (GPU TFLOPs × MFU × 3600)

Where:

- MFU (Model FLOPs Utilization) = 0.3-0.4 **for** typical setups
- GPU TFLOPs = theoretical peak performance

Example Calculations

Example 1: MiniMind-26M (100M tokens)

- Model: 26M parameters
- Dataset: 100M tokens
- GPU: V100 (125 TFLOPs)
- Batch size: 32
- MFU: 0.35

Total FLOPs = 6 × 26M × 100M = 1.56 × 10¹⁶
Actual TFLOPs = 125 × 0.35 = 43.75 TFLOPs
Training seconds = 1.56 × 10¹⁶ ÷ (43.75 × 10¹²) = 356 seconds
Training hours = 356 ÷ 3600 = 0.1 hours (~6 minutes)

For 1B tokens: ~1 hour
For 10B tokens: ~10 hours

Example 2: MiniMind-109M (500M tokens)

- Model: 109M parameters
- Dataset: 500M tokens
- GPU: A100 (312 TFLOPs)
- Batch size: 64
- MFU: 0.40

Total FLOPs = $6 \times 109M \times 500M = 3.27 \times 10^{17}$
Actual TFLOPs = $312 \times 0.40 = 124.8$ TFLOPs
Training hours = $3.27 \times 10^{17} \div (124.8 \times 10^{12} \times 3600) \approx 73$ hours (~3 days)

* * *

Cloud Provider Pricing Comparison

Google Colab

Tier	GPU	Memory	Price	TFLOPs	Best For
Free	T4	16GB	\$0/mo	65	Learning, experiments
Pro	T4/P100	16GB	\$9.99/mo	65-125	Students, hobbyists
Pro+	V100/A100	40GB	\$49.99/mo	125-312	Budget researchers

Limits:

- Free: Limited usage, may disconnect
- Pro: Priority access, longer sessions
- Pro+: Background execution, premium GPUs

Note: Starting July 2025, Google has begun to offer a limited number of completely free, 1-year Colab Pro subscriptions to faculty and students at U.S.-based higher education institutions, check: <https://blog.google/outreach-initiatives/education/colab-higher-education/>

* * *

RunPod (On-Demand Pricing)

GPU	Memory	Price/Hour	TFLOPs	Best For
RTX 4090	24GB	\$0.69	330	Cost-effective training
A40	48GB	\$0.79	150	Medium models
A100 (40GB)	40GB	\$1.69	312	Serious training

GPU	Memory	Price/Hour	TFLOPs	Best For
A100 (80GB)	80GB	\$2.89	312	Large models (>1B)

Features:

- Spot pricing available (30-50% cheaper)
- No commitment
- Easy to scale

* * *

Lambda Labs

GPU	Memory	Price/Hour	TFLOPs	Notes
A100 (40GB)	40GB	\$1.29	312	Reserved instances available
A100 (80GB)	80GB	\$2.49	312	8x GPU clusters available

Features:

- Reserved instances (discounts for long-term)
- Fast networking for multi-GPU
- Good availability

* * *

Paperspace

GPU	Memory	Price/Hour	TFLOPs	Best For
Free GPU	8GB	\$0 (6hr/mo)	25	Quick experiments
P4000	8GB	\$0.51	60	Small models
A100 (80GB)	80GB	\$3.09	312	Enterprise

GPU	Memory	Price/Hour	TFLOPs	Best For
		*	*	*

Vast.ai (Spot Market)

GPU	Memory	Price/Hour	TFLOPs	Notes
RTX 3090	24GB	\$0.29	142	Variable availability
A100 (40GB)	40GB	\$0.89	312	Cheapest A100 option

Note: Prices vary based on demand; can be interrupted

* * *

Training Cost Examples

Scenario 1: MiniMind-26M (20 hours)

Provider	GPU	Total Cost
Google Colab Pro+	V100/A100	\$49.99/mo (unlimited)
RunPod	RTX 4090	\$13.80
Lambda Labs	A100 40GB	\$25.80
Vast.ai	RTX 3090	\$5.80

Recommendation: Vast.ai for single run, Colab Pro+ for multiple experiments

* * *

Scenario 2: MiniMind-109M (100 hours)

Provider	GPU	Total Cost
RunPod	A100 40GB	\$169
Lambda Labs	A100 40GB	\$129
Vast.ai	A100 40GB	\$89

Recommendation: Lambda Labs (better availability) or Vast.ai (lowest cost)

* * *

Scenario 3: Fine-tuning 7B Model (40 hours)

Provider	GPU	Total Cost
RunPod	A100 80GB	\$115.60
Lambda Labs	A100 80GB	\$99.60

Recommendation: Lambda Labs for reliability

* * *

GPU Memory Requirements

Model Memory by Precision

Model Size	FP32	FP16	INT8	INT4	Inference (INT4)
26M	105 MB	53 MB	26 MB	13 MB	~50 MB total
109M	438 MB	219 MB	109 MB	55 MB	~150 MB total
218M	873 MB	437 MB	218 MB	109 MB	~250 MB total
336M	1.3 GB	673 MB	337 MB	168 MB	~400 MB total
1B	4.0 GB	2.0 GB	1.0 GB	500 MB	~1.5 GB total
3B	12.0 GB	6.0 GB	3.0 GB	1.5 GB	~4 GB total
7B	28.0 GB	14.0 GB	7.0 GB	3.5 GB	~8 GB total

* * *

Training Memory Requirements

Formula: Total = Model + Optimizer + Gradients + Activations

Model Size	Batch=1 (GB)	Batch=8 (GB)	Batch=32 (GB)	Recommended GPU
26M	2	4	8	Any 8GB+ GPU
109M	5	10	20	RTX 3060 (12GB)
218M	10	18	35	RTX 4090 (24GB)
336M	15	25	50+	A100 40GB
1B	30+	60+	-	A100 80GB
7B	80+	-	-	Multiple A100s

Note: With gradient accumulation, you can use smaller batches and accumulate gradients

* * *

Memory Reduction Techniques

Technique	Memory Savings	Speed Impact	Complexity
Mixed Precision (FP16)	50%	1.5-2x faster	Easy
Gradient Accumulation	Scales with batch	Neutral	Easy
Gradient Checkpointing	30-50%	20% slower	Medium
LoRA Fine-tuning	90%+	Minimal	Easy
8-bit Optimizers	25%	Minimal	Easy
Flash Attention	20-30%	2-3x faster	Medium

* * *

Cost Examples by User Type

PhD Student / Academic Researcher

Budget: \$50-200/month

Recommended Setup:

- Google Colab Pro+ (\$50/month) for exploration
- Vast.ai spot instances for longer runs (\$0.29-0.89/hr)
- University cluster (free if available)

Example Projects:

1. MiniMind-26M: ~\$10-20 total (Colab Pro+ or 20hrs on Vast.ai)
2. MiniMind-109M: ~\$50-100 total (100hrs on Vast.ai RTX 3090)
3. Fine-tuning 1B model: ~\$150-200 (multi-GPU on Lambda)

Annual Cost: \$600-2,400

* * *

Independent Researcher / Hobbyist

Budget: \$100-500/month

Recommended Setup:

- RunPod for regular experiments (\$0.69-1.69/hr)
- Lambda Labs for serious training runs (\$1.29/hr)
- Local GPU for inference (RTX 3060/4060 Ti - \$300-500)

Example Projects:

1. Custom chatbot (MiniMind-109M): ~\$80 training, \$10/mo hosting
2. Domain-specific model (512M): ~\$300 training
3. Multiple experiments: \$200-400/month on-demand

Annual Cost: \$1,200-6,000 (plus \$300-500 for local GPU)

* * *

Appendix B: Quick Reference

Model Size Comparison Table

Model	Params	Layers	Hidden	Heads	Vocab	Context	Train Time*
MiniMind-26M	26M	6	512	8	6,400	512	20 hrs
MiniMind-109M	109M	12	768	12	6,400	512	100 hrs
MiniMind-218M	218M	16	1024	16	6,400	512	200 hrs
MiniMind-336M	336M	20	1152	12	6,400	512	300 hrs
GPT-2 Small	124M	12	768	12	50,257	1024	~200 hrs
GPT-2 Medium	355M	24	1024	16	50,257	1024	~500 hrs
GPT-2 Large	774M	36	1280	20	50,257	1024	~1,000 hrs
GPT-2 XL	1.5B	48	1600	25	50,257	1024	~2,000 hrs
Llama-2-7B	7B	32	4096	32	32,000	4096	~10,000 hrs

*Train time on single A100 (40GB) with typical dataset

* * *

GPT-2 vs MiniMind Architecture Comparison

Feature	GPT-2	MiniMind	Why Different?
Tokenizer	BPE (50K vocab)	BPE (6.4K vocab)	Smaller vocab = faster, less memory
Position Encoding	Learned	Learned	Same approach
Attention	Multi-head	Multi-head	Same approach
Activation	GELU	GELU	Same approach
Normalization	LayerNorm	RMSNorm	RMSNorm is faster, simpler
Context Length	1024 tokens	512 tokens	Shorter context for efficiency
Dropout	Yes (0.1)	Optional	Can skip for small models
Bias in Linear	Yes	No (optional)	Modern trend: no bias
Initialization	N(0, 0.02)	N(0, 0.02)	Same approach
Vocab Size	50,257	6,400	Focused vocabulary

Feature	GPT-2	MiniMind	Why Different?
---------	-------	----------	----------------

Performance Comparison (MiniMind-109M vs GPT-2-124M)

- **Training Speed:** MiniMind ~15% faster (smaller vocab, RMSNorm)
- **Memory:** MiniMind uses ~20% less memory
- **Quality:** Comparable on same-size datasets
- **Inference:** MiniMind ~10% faster

When to Choose Each

Choose GPT-2 when:

- You need maximum compatibility
- Using existing GPT-2 checkpoints
- Targeting English-only tasks
- Following established research

Choose MiniMind when:

- Training from scratch
- Resource-constrained
- Multilingual support needed
- Learning architecture design
- Want modern architecture choices

* * *

Hyperparameter Cheat Sheet

Pretraining

Parameter	Small (< 100M)	Medium (100M-500M)	Large (>500M)	Rule of Thumb
Learning Rate	3e-4 to 6e-4	1e-4 to 3e-4	1e-4 to 2e-4	Larger models need smaller LR
Batch Size	32-128	16-64	4-32	As large as GPU allows
Warmup Steps	2,000-5,000	5,000-10,000	10,000-20,000	1-5% of total steps
Weight Decay	0.1	0.1	0.1-0.3	Standard is 0.1
Dropout	0.0	0.1	0.1-0.2	More data = less dropout
Grad Clip	1.0	1.0	1.0	Always use gradient clipping

* * *

Supervised Fine-Tuning (SFT)

Parameter	From Scratch	From Pretrained	Notes
Learning Rate	3e-4	1e-5 to 5e-5	10-100x smaller than pretraining
Epochs	10-20	1-5	Watch for overfitting
Batch Size	8-32	8-32	Smaller than pretraining
Warmup Ratio	0.1	0.03	Percentage of total steps
Weight Decay	0.01	0.01	Lower than pretraining

Dataset Size Guidelines:

- Large (>100K): 1-3 epochs
- Medium (10K-100K): 3-5 epochs
- Small (< 10K): 5-10 epochs (watch overfitting!)

* * *

DPO Alignment

Parameter	Standard	Conservative	Aggressive	Notes
Learning Rate	5e-6	1e-6	1e-5	Very small to preserve base
Beta	0.1	0.5	0.01	Higher = stay closer to reference
Epochs	1-2	1	3	Usually don't need many
Batch Size	8-16	8-16	8-16	Standard sizes

Beta Parameter:

- High beta (0.5): Conservative, stays close to reference
- Medium beta (0.1): Standard, balanced
- Low beta (0.01): Aggressive, diverges more

* * *

LoRA Fine-Tuning

Parameter	Small	Medium	Large	Notes
Rank (r)	4-8	16-32	64-128	Higher rank = more parameters
Alpha	8-16	32-64	128-256	Usually 2×r
Learning Rate	1e-4 to 3e-4	1e-4 to 3e-4	1e-4 to 3e-4	Higher than full fine-tuning
Target Modules	q,v	q,k,v,o	all	Which attention layers to adapt

Rank Selection:

- r=4: Very efficient, may underfit
- r=8-16: Sweet spot for most tasks
- r=32-64: High quality, still efficient
- r=128+: Approaching full fine-tuning

* * *

Pretraining vs SFT vs DPO Comparison

Aspect	Pretraining	SFT	DPO
Goal	Learn language patterns	Learn specific tasks	Align with preferences
Data Type	Raw text	Instruction-response pairs	Preference pairs (chosen/rejected)
Data Size	100M - 100B+ tokens	10K - 1M pairs	10K - 100K pairs
Learning Rate	High (3e-4)	Medium (5e-5)	Low (5e-6)
Duration	Days to weeks	Hours to days	Hours
Cost	\$\$\$\$	\$\$	\$
Purpose	Foundation	Capability	Safety/alignment
Starting Point	Random weights	Pretrained model	SFT model
Overfitting Risk	Low (huge data)	Medium	High (small data)
Output Quality	Language model	Task-specific model	Aligned model

When to Use Each

Pretraining:

- Building model from scratch
- Have massive compute budget
- Novel architecture or domain
- Don't have billions of tokens
- Limited compute

Supervised Fine-Tuning:

- Have pretrained model
- Need task-specific capability
- 10K+ quality examples
- Most common use case
- Trying to change fundamental knowledge

DPO Alignment:

- Have SFT model
- Need safety/preference alignment
- Have preference data
- Want to avoid complex RLHF
- Don't have preference pairs

Typical Pipeline

- 1. Pretraining (or use existing model like GPT-2)
↓
- 2. Supervised Fine-Tuning on your task data
↓
- 3. DP0 for alignment (optional but recommended)
↓
- 4. Deploy to production

* * *

Troubleshooting Guide

Training Issues

Loss is NaN or Infinity

Symptoms:

- Loss becomes NaN after some steps
- Loss explodes to infinity

Causes & Solutions:

Cause	Solution
Learning rate too high	Reduce LR by 10x
Gradient explosion	Enable gradient clipping: max_norm=1.0
Numerical instability	Use mixed precision (fp16/bf16)
Bad initialization	Check weight initialization
Division by zero	Check model code for /0 errors

* * *

Loss Not Decreasing

Symptoms:

- Loss stays flat
- Loss decreases very slowly

Causes & Solutions:

Cause	Solution
Learning rate too low	Increase LR (try 3x-10x)
Model too small	Try larger model
Data issues	Verify data loading correctly
Wrong loss function	Check loss calculation
No warmup	Add learning rate warmup

* * *

Overfitting

Symptoms:

- Train loss decreases but val loss increases
- Large gap between train and val loss

Solutions:

Technique	Effect	When to Use
Early stopping	Stop before overfitting	Always
Add dropout (0.1-0.2)	Regularization	Medium/large models
Increase weight decay	Regularization	All models
Get more data	More training signal	When possible
Use LoRA	Fewer trainable params	Limited data
Data augmentation	Effective data increase	NLP: backtranslation, paraphrasing

* * *

Memory Issues

CUDA Out of Memory

Solutions (in order of preference):

1. **Reduce batch size** - Easiest, always works

- 2. **Use gradient accumulation** - Simulate larger batch
- 3. **Enable gradient checkpointing** - Trade compute for memory
- 4. **Use mixed precision (fp16/bf16)** - 50% memory savings
- 5. **Reduce sequence length** - If task allows
- 6. **Try LoRA/QLoRA** - 90%+ memory savings
- 7. **Use 8-bit optimizers** - 25% savings on optimizer states

Example: Gradient Accumulation

```
# Instead of batch_size=32 (OOM)
batch_size = 8
gradient_accumulation_steps = 4 # Effective batch = 32
```

* * *

Slow Training

Symptoms:

- Training much slower than expected
- Low GPU utilization

Causes & Solutions:

Cause	Solution	Impact
Data loading bottleneck	Increase num_workers in DataLoader	2-3x faster
CPU-GPU transfer	Use pin_memory=True	10-20% faster
Inefficient code	Profile with torch.profiler	Varies
No optimization	Use torch.compile() (PyTorch 2.0+)	20-30% faster
Small model on GPU	May be faster on CPU	Check both

Check GPU Utilization:

```
nvidia-smi -l 1 # Monitor every second
```

Should see >80% GPU utilization during training

* * *

Generation Issues

Repetitive Text

Symptoms:

- “the the the the...”
- Repeating phrases

Solutions:

Parameter	Default	Try	Effect
Temperature	1.0	0.7-1.2	Higher = more random
Top-p	0.9	0.85-0.95	Nucleus sampling
Repetition penalty	1.0	1.1-1.3	Penalize repetition
Top-k	50	30-100	Limit choices

* * *

Nonsense Output

Symptoms:

- Incoherent text
- Random characters

Solutions:

Cause	Solution
Temperature too high	Lower to 0.3-0.7
Model undertrained	Train longer
Wrong tokenizer	Verify tokenizer matches model
Model not loaded	Check model loaded correctly

* * *

Doesn't Follow Instructions

Symptoms:

- Ignores prompts
- Wrong task

Solutions:

1. **Do SFT training** - Model needs instruction tuning
2. **Improve instruction dataset** - Need quality examples
3. **Use consistent prompt format** - e.g., "User: X\nAssistant: Y"
4. **Add system prompts** - Set behavior expectations
5. **More instruction examples** - Need diversity

* * *

Data Issues

Data Loading Errors

Common fixes:

- Check file paths are correct
- Verify JSON/JSONL format is valid
- Ensure encoding is UTF-8
- Check for corrupted files
- Validate data schema

Example: Validate JSON

```
import json

try:
    with open('data.json', 'r') as f:
        data = json.load(f)
    print(f"✓ Valid JSON with {len(data)} items")
except json.JSONDecodeError as e:
    print(f"✗ Invalid JSON: {e}")
```

* * *

Tokenizer Issues

Symptoms:

- Weird tokens
- Wrong text output
- Crashes during tokenization

Solutions:

Issue	Solution
Missing special tokens	Set bos_token, eos_token, pad_token
Wrong vocabulary	Rebuild tokenizer on your data
Encoding errors	Use UTF-8 encoding
Max length issues	Set appropriate max_length
Tokenizer mismatch	Verify tokenizer matches model

* * *

Debugging Checklist

When something goes wrong:

1. **Check logs** for error messages
2. **Print data samples** - Verify data loading
3. **Check model architecture** - Matches config?
4. **Verify hyperparameters** - In reasonable ranges?
5. **Test tiny dataset** - Should overfit quickly
6. **Compare with baseline** - Is it worse than random?
7. **Search error message** - Google + “pytorch”
8. **Check GitHub issues** - Known problem?
9. **Ask for help** - Forums with full error trace

* * *

Decision Tree: SLMs vs Giant LLMs

Decision Criteria Table

Criteria	Use SLM	Use Giant LLM	Use API
Budget	<\$1K	>\$10K	\$100-1000/mo
Latency Needs	< 100ms	Flexible	100-2000ms
Data Privacy	Critical	Moderate	Not critical
Customization	High	High	Low-Medium
Deployment	Edge/Mobile	Cloud	Cloud
Team Size	1-3 people	5+ people	Any
Time to Deploy	Days-Weeks	Months	Hours
Data Availability	10K-1M	10M+	N/A

Use SLMs When:

- **Latency matters** - Need < 100ms response time
- **Privacy critical** - Can't send data to external APIs
- **Limited budget** - <\$1,000 for training
- **Edge deployment** - Running on devices/edge servers
- **Domain-specific** - Narrow, well-defined task
- **Full control needed** - Want to own entire stack
- **Small team** - 1-3 ML engineers
- **Quick iteration** - Need fast experiment cycles

Example Use Cases:

- Code completion in IDE
- Customer service chatbot (specific domain)
- On-device translation
- Medical Q&A (HIPAA compliance)
- Autocomplete/suggestions
- IoT devices

* * *

Use Giant LLMs When:

- **Complex reasoning** - Need GPT-4 level capabilities
- **Broad knowledge** - Cross-domain questions
- **Research project** - Exploring capabilities
- **Have resources** - \$10K+ budget, large team
- **Novel research** - Creating new capabilities
- **Not time-critical** - Latency >1 second acceptable

Example Use Cases:

- Research chatbot (all topics)
- Complex code generation
- Creative writing assistant
- General knowledge QA
- Novel AI research
- Advanced reasoning tasks

* * *

Use APIs When:

- **Quick prototype** - Need results in hours
- **Limited ML expertise** - Don't want to manage models
- **Variable load** - Traffic fluctuates wildly
- **Latest capabilities** - Want cutting-edge performance
- **No privacy concerns** - Can send data externally
- **Budget for it** - \$100-1000/month acceptable

Example Use Cases:

- Consumer apps (non-sensitive)
- Internal tools
- Prototypes/MVPs
- Startups (early stage)
- Low-volume applications

* * *

Hybrid Approach (Recommended)

Phase 1: Start **with** APIs **for** prototype

|

Phase 2: If successful, fine-tune **open** source model

|

Phase 3: If privacy/cost issue, train custom SLM

|

Production: SLM + API fallback **for** edge cases

Best of both worlds:

- Fast iteration with APIs
- Cost-effective with SLMs
- Fallback for complex queries

* * *

Appendix C: Dataset & Model Zoo

Curated Datasets by Domain

All downloadable links are also available at the Chapter 13 Google Colab notebook.

Pretraining: English Corpora

Dataset	Size	Tokens	Quality	License	Best For
The Pile	825 GB	~300B	High	Mixed	General English pretraining
C4	750 GB	~156B	Medium-High	ODC-BY	Web-like text
Wikipedia	20 GB	~3B	Very High	CC BY-SA 3.0	Factual knowledge
BookCorpus	5 GB	~800M	High	Varies	Long-form narrative
OpenWebText	38 GB	~8B	High	Public Domain	Diverse web text

Recommended Pretrained Models

Small Models (<1B parameters)

Model	Size	Context	License	Best For	URL
MiniMind-109M	109M	512	Apache 2.0	Learning, edge	minimind
GPT-2-124M	124M	1024	MIT	English baseline	gpt2
DistilGPT-2	82M	1024	Apache 2.0	Fast inference	distilgpt2
TinyLlama-1.1B	1.1B	2048	Apache 2.0	Efficient chat	TinyLlama
Phi-1.5	1.3B	2048	MIT	Code, reasoning	
microsoft/phi-1_5					
Pythia-1B	1B	2048	Apache 2.0	Research	
EleutherAI/pythia-1b					

* * *

Medium Models (1B-7B)

Model	Size	Context	License	Best For	URL
Llama-2-7B	7B	4096	Llama 2	General purpose	
meta-llama/Llama-2-7b-hf					
Mistral-7B	7B	8192	Apache 2.0	Strong performance	
mistralai/Mistral-7B-v0.1					
Phi-2	2.7B	2048	MIT	Reasoning, code	
microsoft/phi-2					
Gemma-2B	2B	8192	Gemma License	Multilingual	
google/gemma-2b					
Qwen-1.8B	1.8B	2048	Custom	Chinese + English	
Qwen/Qwen-1_8B					

* * *

Specialized Models

Model	Size	Specialty	Best For	URL
CodeLlama-7B	7B	Code	Code generation	
codellama/CodeLlama-7b-hf				
Meditron-7B	7B	Medical	Medical tasks	
epfl-llm/meditron-7b				
WizardMath-7B	7B	Math	Math problems	
WizardLM/WizardMath-7B-V1.0				
Falcon-7B-Instruct	7B	Instructions	Instruction following	tiiuae/falcon-7b-instruct

Model Selection Guide

For Learning

Recommended: MiniMind-26M or GPT-2-124M

Why:

- Small enough to train on single GPU
- Well-documented
- Fast iteration
- Complete training pipeline

* * *

For Production (English)

Recommended: Mistral-7B (quality) or TinyLlama-1.1B (efficiency)

Why:

- Mistral: Best performance for size
- TinyLlama: Fast, efficient, good quality

* * *

For Production (Multilingual)

Recommended: Gemma-2B or Qwen-1.8B

Why:

- Good multilingual support
- Efficient size
- Strong performance

* * *

For Code

Recommended: CodeLlama-7B or Phi-2

Why:

- CodeLlama: Specialized for code
- Phi-2: Great reasoning, smaller

* * *

For Domain-Specific

Recommended: Start with Mistral/Llama and fine-tune

Why:

- Strong base model
- Good fine-tuning performance
- Lots of community support

* * *

For Research

Recommended: Pythia series

Why:

- Fully documented training
- Multiple checkpoints during training
- Reproducible
- Research-grade

* * *

Code Repositories & Tools

Training Frameworks

1. MiniMind (This book!)

- **URL:** <https://github.com/jingyaogong/minimind>
- **Focus:** Educational, from-scratch implementation
- **Best for:** Learning how LLMs work

2. nanoGPT (Andrej Karpathy)

- **URL:** <https://github.com/karpathy/nanoGPT>
- **Focus:** Minimal, clean GPT implementation
- **Best for:** Understanding fundamentals

3. Lit-GPT (Lightning AI)

- **URL:** <https://github.com/Lightning-AI/lit-gpt>
- **Focus:** Production-ready, multiple architectures
- **Best for:** Training various model types

4. GPT-NeoX (EleutherAI)

- **URL:** <https://github.com/EleutherAI/gpt-neox>
- **Focus:** Large-scale training
- **Best for:** Research-grade training

* * *

Fine-Tuning Tools

1. Axolotl

- **URL:** github.com/OpenAccess-AI-Collective/axolotl
- **Features:** Comprehensive, many techniques
- **Best for:** Flexible fine-tuning

2. LLaMA-Factory

- **URL:** <https://github.com/hiyouga/LLaMA-Factory>
- **Features:** Easy framework, Web UI
- **Best for:** Quick fine-tuning

3. Hugging Face PEFT

- **URL:** <https://github.com/huggingface/peft>

- **Features:** LoRA, prefix tuning, etc.
- **Best for:** Parameter-efficient fine-tuning

* * *

Inference & Deployment

1. llama.cpp

- **URL:** <https://github.com/ggerganov/llama.cpp>
- **Features:** CPU inference, quantization
- **Best for:** Local/edge deployment

2. vLLM

- **URL:** <https://github.com/vllm-project/vllm>
- **Features:** Fast GPU inference
- **Best for:** Production GPU serving

3. Text Generation Inference (HF)

- **URL:** github.com/huggingface/text-generation-inference
- **Features:** Production serving, optimized
- **Best for:** Enterprise deployment

* * *

Educational Resources

1. Andrej Karpathy's Lectures

- Neural Networks: Zero to Hero series
- **URL:** YouTube + GitHub repos
- **Best for:** Deep understanding of fundamentals

2. Fast.ai NLP Course

- Practical deep learning
- **URL:** course.fast.ai

- **Best for:** Practical applications

3. Hugging Face Course

- Comprehensive NLP course
- **URL:** huggingface.co/course
- **Best for:** Using transformers library

This appendix section provides:

- **Resource Calculator** - Estimate costs and requirements
- **Quick Reference** - Tables, comparisons, troubleshooting
- **Implementation Details** - Complete MiniMind specifications
- **Dataset & Model Zoo** - Curated resources for your projects

End of Appendices

Acknowledgements

This book would not have been possible without the support, encouragement, and opportunities provided by the family and communities around me.

I would first like to express my deepest gratitude to the Data Science and AI Academy and the Bioinformatics Research Center at NC State, and the Research Triangle AI Society. Over the past several years, these organizations have given me the privilege of teaching courses, giving talks, leading workshops, and training hundreds of students, researchers, and professionals. The iterative cycle of teaching, practice, and refinement directly shaped every chapter of this book. Without these experiences and the platforms they provided, this work would not exist.

I am grateful to the open source community, particularly the contributors to PyTorch, GitHub, Hugging Face, YouTube, and the researchers who make their work publicly available. This book stands on your shoulders.

Special thanks to Professor DK Xu from Computer Science Dept, Dr. Yu Yang, Senior Data Scientist from NetApp, Dr. Ruiwen Zhang, Senior Research Statistician at SAS, and Mr. Tarik Kaoutar (Gao Dalie) a graduate student at NCSU who generously reviewed early drafts and provided thoughtful, constructive feedback. Your insights greatly improved the clarity, accuracy, and completeness of the material. Thanks also to the early readers and students who worked through draft chapters and helped refine the practical exercises.

A special thank you goes to my wife and children. Thank you for your patience, understanding, and love during the countless evenings and weekends devoted to writing, coding, and refining this work. Your support made this book possible.

To everyone who contributed—through teaching, collaboration, inspiration, or simply encouragement—thank you. This book is as much yours as it is mine.
